**Measurement of  $t_0$  using APA crossing tracks  
(work in progress)**

# Motivation

- ❑ The Photon detector system will provide the  $t_0$  timing of the events relative to the TPC.
- ❑ We are working on the measurement of  $\Delta t$  for the events which crosses the APA.
- ❑ Spatial separation ( $\Delta X$ ) between the positive (long drift) and negative (short drift) segment of a crossing track will give information to measure  $\Delta t$ .
- ❑ Angle between the two segments of a crossing track is also important parameter to measure.

# Event selection

- ❑ We have started our analysis with AntiMuonCutEvents\_LSU\_dune35t sample because these are single muon event with  $t=0$ .
- ❑ At first, we have checked the starting and ending position of all the tracks.

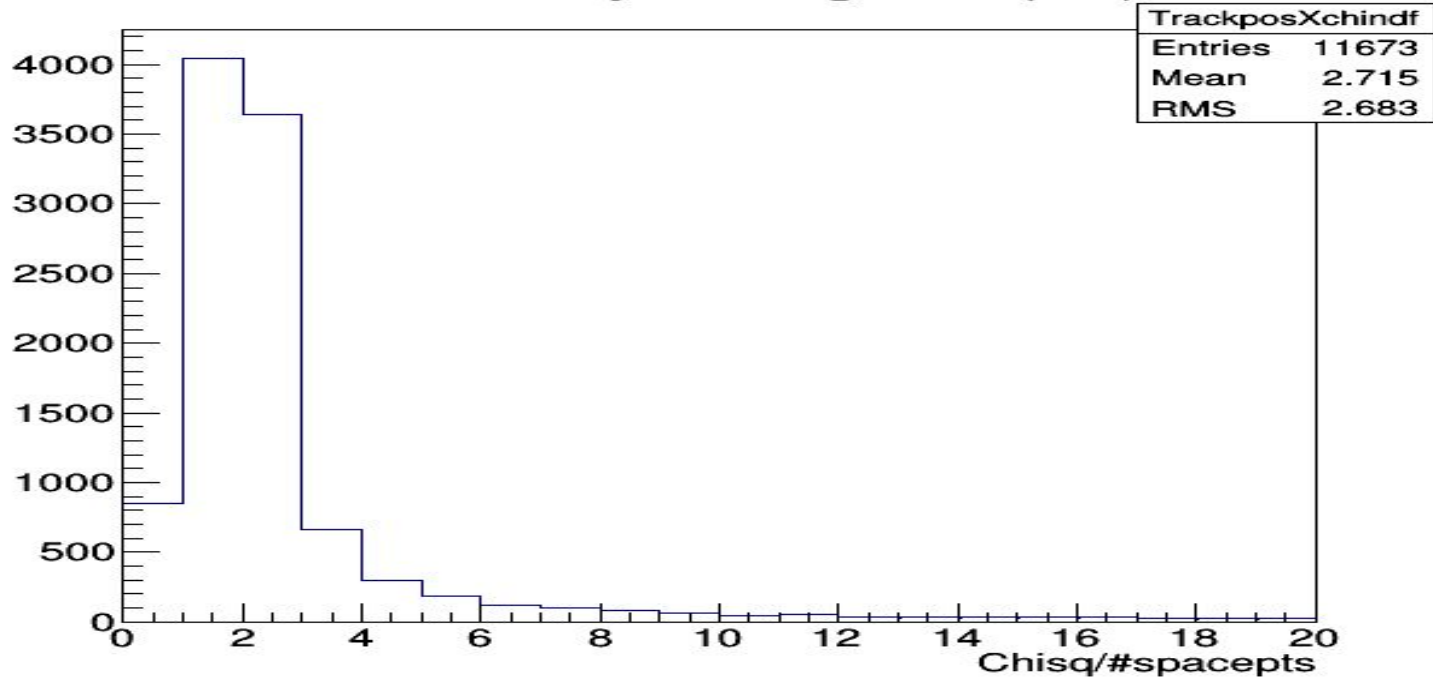

# Track fitting and chisq

- ❑ We have selected tracks that crosses APA, we have splitted them into two segments along long and short drift.
- ❑ We have also selected the tracks which are only in the long drift, only in the short drift to check a good track.
- ❑ We have fitted the tracks using 3D line fit.
- ❑ The fitting method is
$$X = p[0] + p[1] t$$
$$Y = p[2] + p[3] t$$
$$Z = t$$
- ❑ Chisq is divided with no of space points and is plotted for different cases.

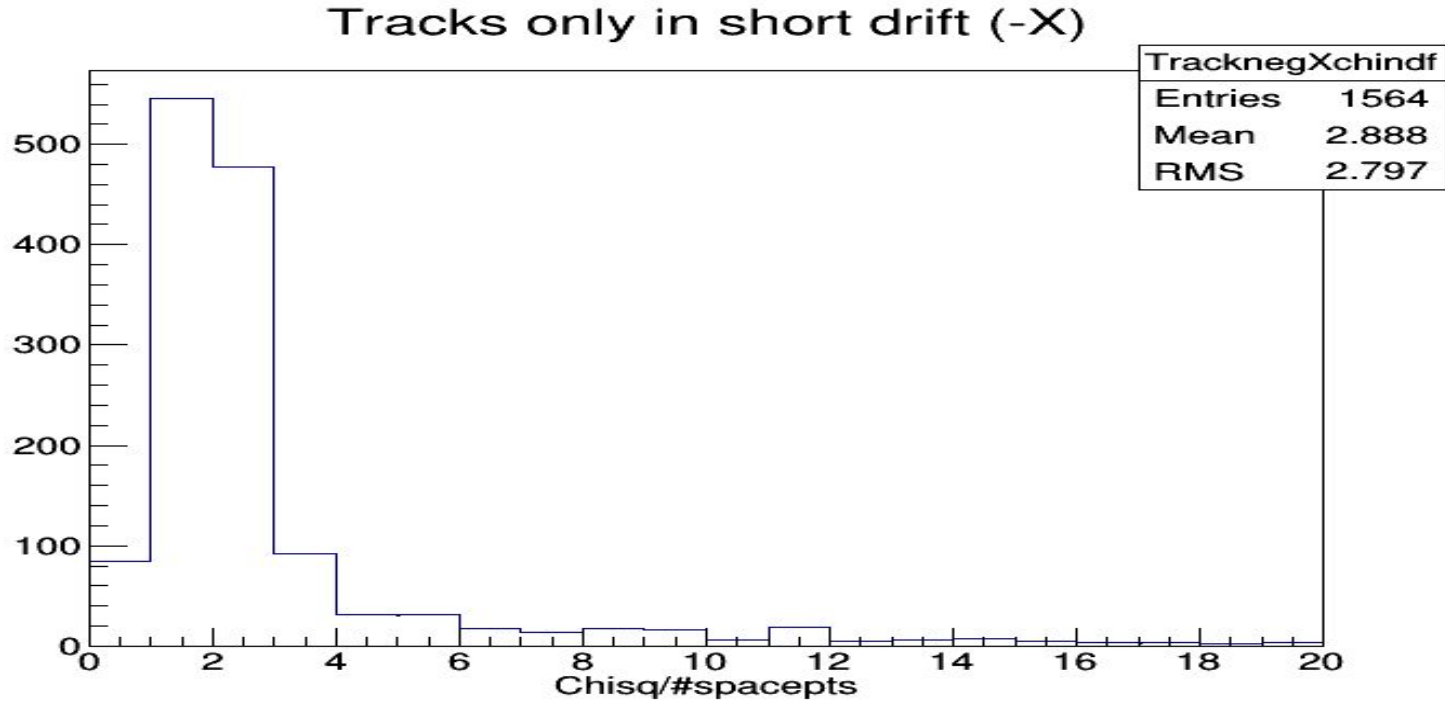

# (Chisq/#spts) distribution(only in long drift)

Tracks only in long-drift (+X)

# (Chisq/#spts) distribution(only in short drift)

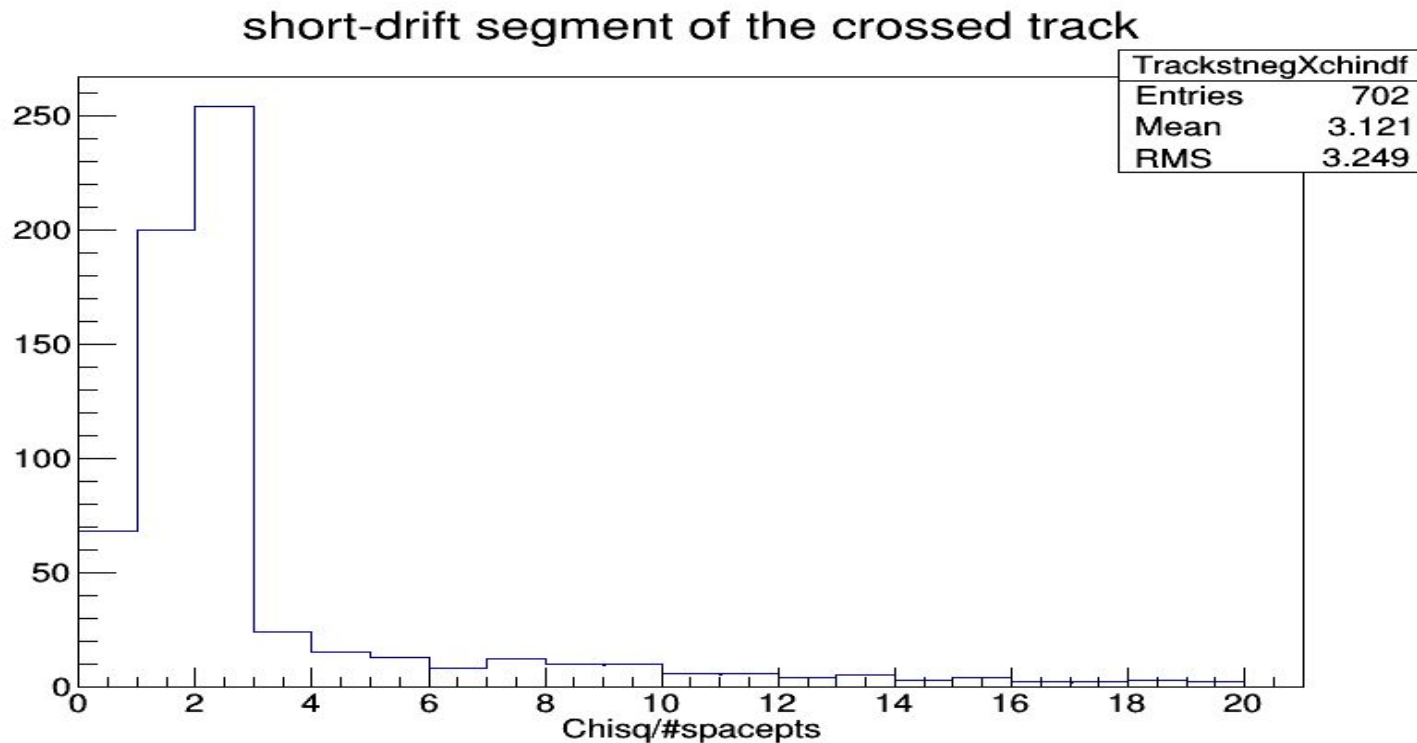

# (Chisq/#spts)distribution (long drift of crossing track)

Long-drift segment of the crossed track

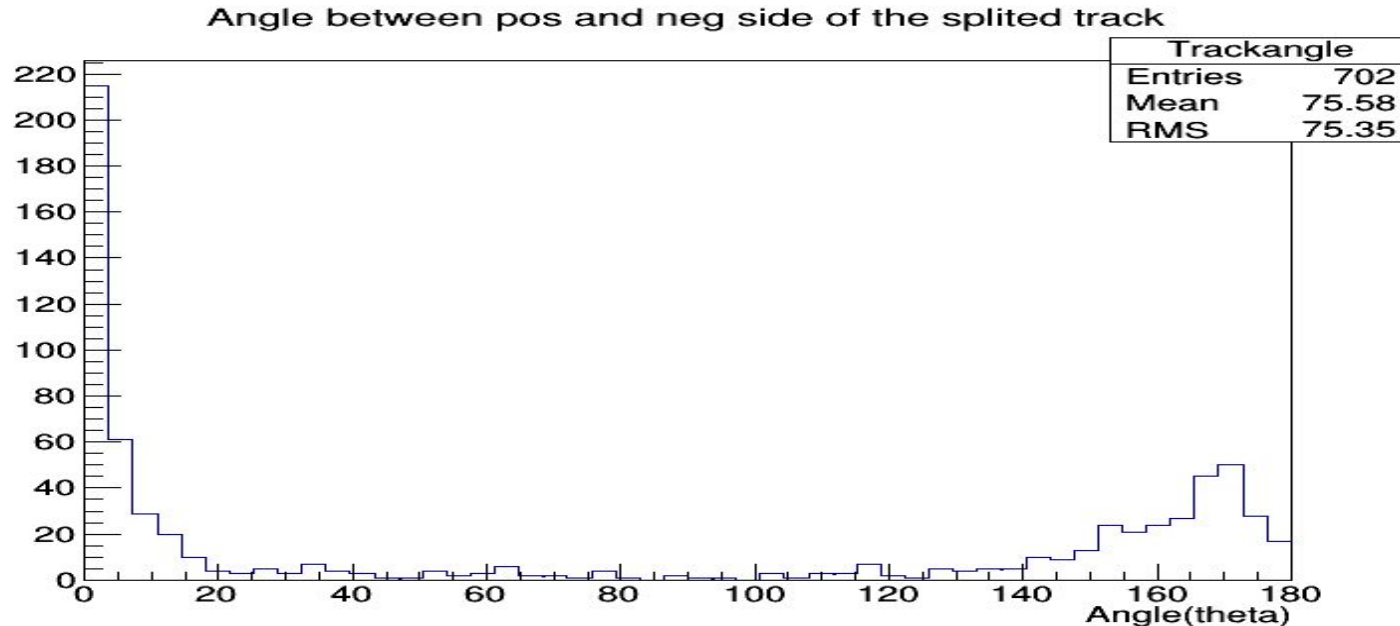

# Chisq/#spts distribution(short drift of crossing track)

# Angle between the two segments of crossing tracks

- ❑ Angle between the long and short drift part of a crossed track is defined as  $\theta = \arccos(n_1 \cdot n_2)$ ;
- ❑  $n \rightarrow$  unit vector of the segments of crossing track

# Angle distribution after (chisq/#spts <3) cut

Angle distribution after chisq cut

# Delta X between two segments of crossing track

An extra parameter in the fit dx is added each iteration for positive drift and is subtracted from negative drift points.

Delta X between pos and neg part of splited track

# Delta X after (chisq/#spts <3)cut

## Delta X after chisq cut

# Future plan

- ❑ We will now consider the flashtime from Photon detector and drift velocity and compare with the delta X.
- ❑ We will work on cry sample.
- ❑ We will have to improve event selection.
- ❑ We will also try to understand the unit vector of the segments of track along x, y,z, and angle with respect to electric field.
