Mass Dependence of Higgs Production at Large Transverse Momentum

Monday, 31 July 2017 14:30 (20 minutes)

The transverse momentum distribution of the Higgs at large P_T is complicated by its dependence on three important energy scales: P_T , the top quark mass m_t , and the Higgs mass m_H . A strategy for simplifying the calculation of the cross section at large P_T is to calculate only the leading terms in its expansion in m_t^2/P_T^2 and/or m_H^2/P_T^2 . The expansion of the cross section in inverse powers of P_T is complicated by logarithms of P_T and by mass singularities. In this work, we consider the top-quark-loop contribution to the subprocess $q\bar{q} \rightarrow H + g$ at leading order in α_s , which proceeds through a top quark loop. We show that the leading power of $1/P_T^2$ can be expressed in the form of a factorization formula that separates the large scale P_T from the scale of the masses. All the dependence on m_t and m_H can be factorized into fragmentation amplitudes for $t\bar{t} \rightarrow H$ and for $t\bar{t} \rightarrow g$ and an endpoint contribution. This factorization approach will be useful for calculating the P_T distribution at large P_T to next-to-leading order in α_s .
