

The slow neutron capture process and CEMP-*s* stars

Amanda Karakas

School of Physics & Astronomy, Monash University, Australia

Carbon enhanced metal-poor stars

- Roughly 10-20% of old halo stars are C-rich ($[C/Fe] > 1$; Cohen et al. 2005; Carollo et al. 2011)
- Of these $\sim 2/3$ show enrichments in heavier elements (e.g., Aoki et al. 2007), with CEMP-s defined in Beers & Christlieb (2005)

Using the data and classification of Masseron et al. (2010)

The puzzle of the CEMP-s/r stars

- About 50% of CEMP stars with an s-process signature also show an enrichment in r-process elements

→ See Melanie Hampel's talk

Definition of CEMP s/r:

- $[\text{Eu}/\text{Fe}] > 1$
- $[\text{Ba}/\text{Eu}] > 0$ but lower than for CEMP-s
- Appear distinct from CEMP-s (e.g., talks by Beers, Aoki etc)

The “other” CEMP-s stars

- In the Small and Large Magellanic Cloud, a population of very s-process enriched post-AGB stars have been discovered
- These are also metal-poor ($[Fe/H] < -1$) and carbon-rich

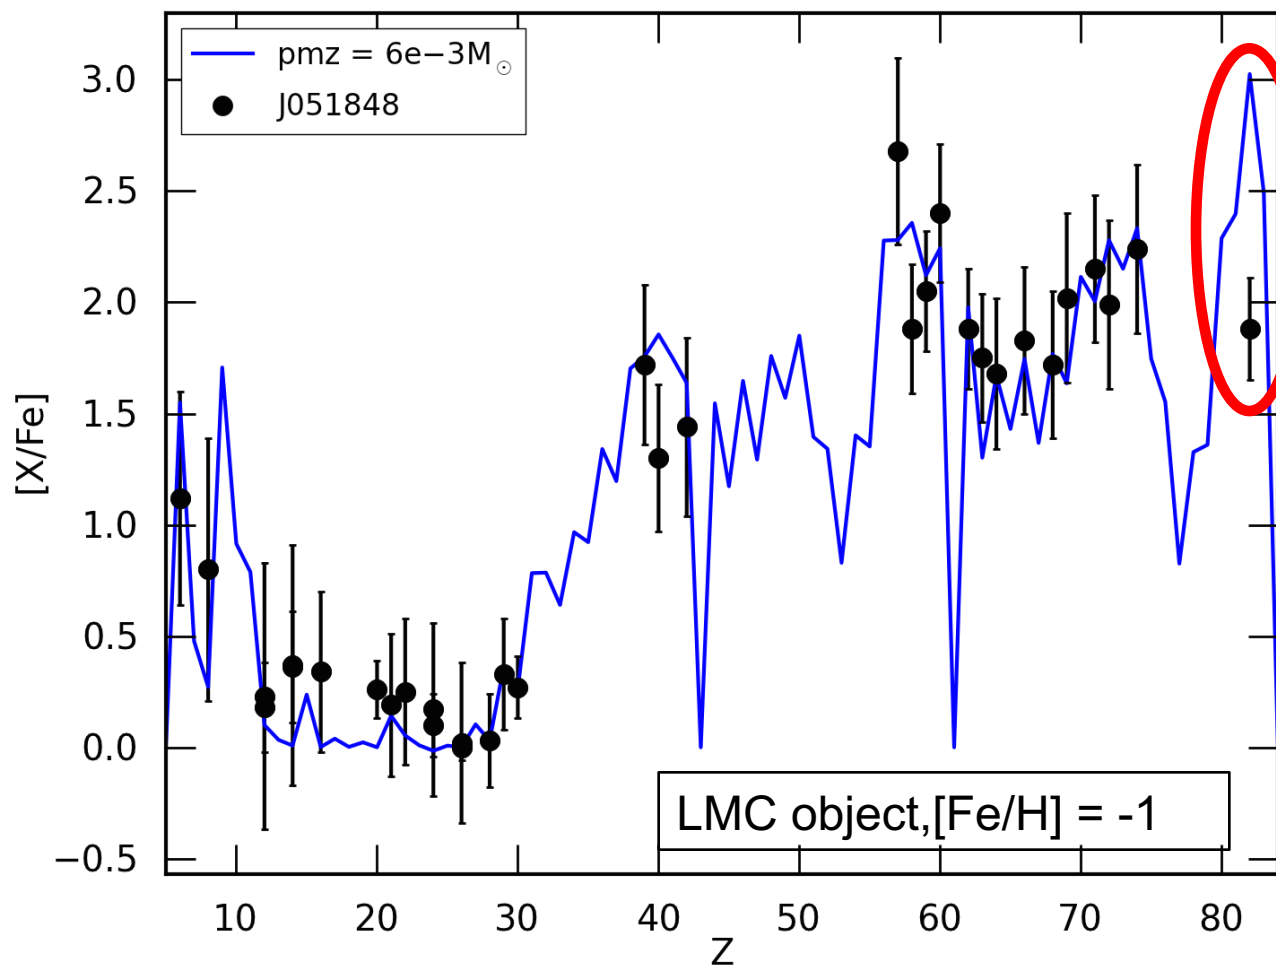

The abundance pattern of the post-AGB star J004441.04 ($[Fe/H] = -1.4$) in comparison with model predictions from various groups

From De Smedt et al. (2012)

The “other” CEMP-s stars

- Evolved from stars of low-mass of $\sim 1.3M_{\text{sun}}$ with $[\text{Fe}/\text{H}] \lesssim -1$ (De Smedt et al. 2012, 2014, 2016; van Aarle et al. 2013)

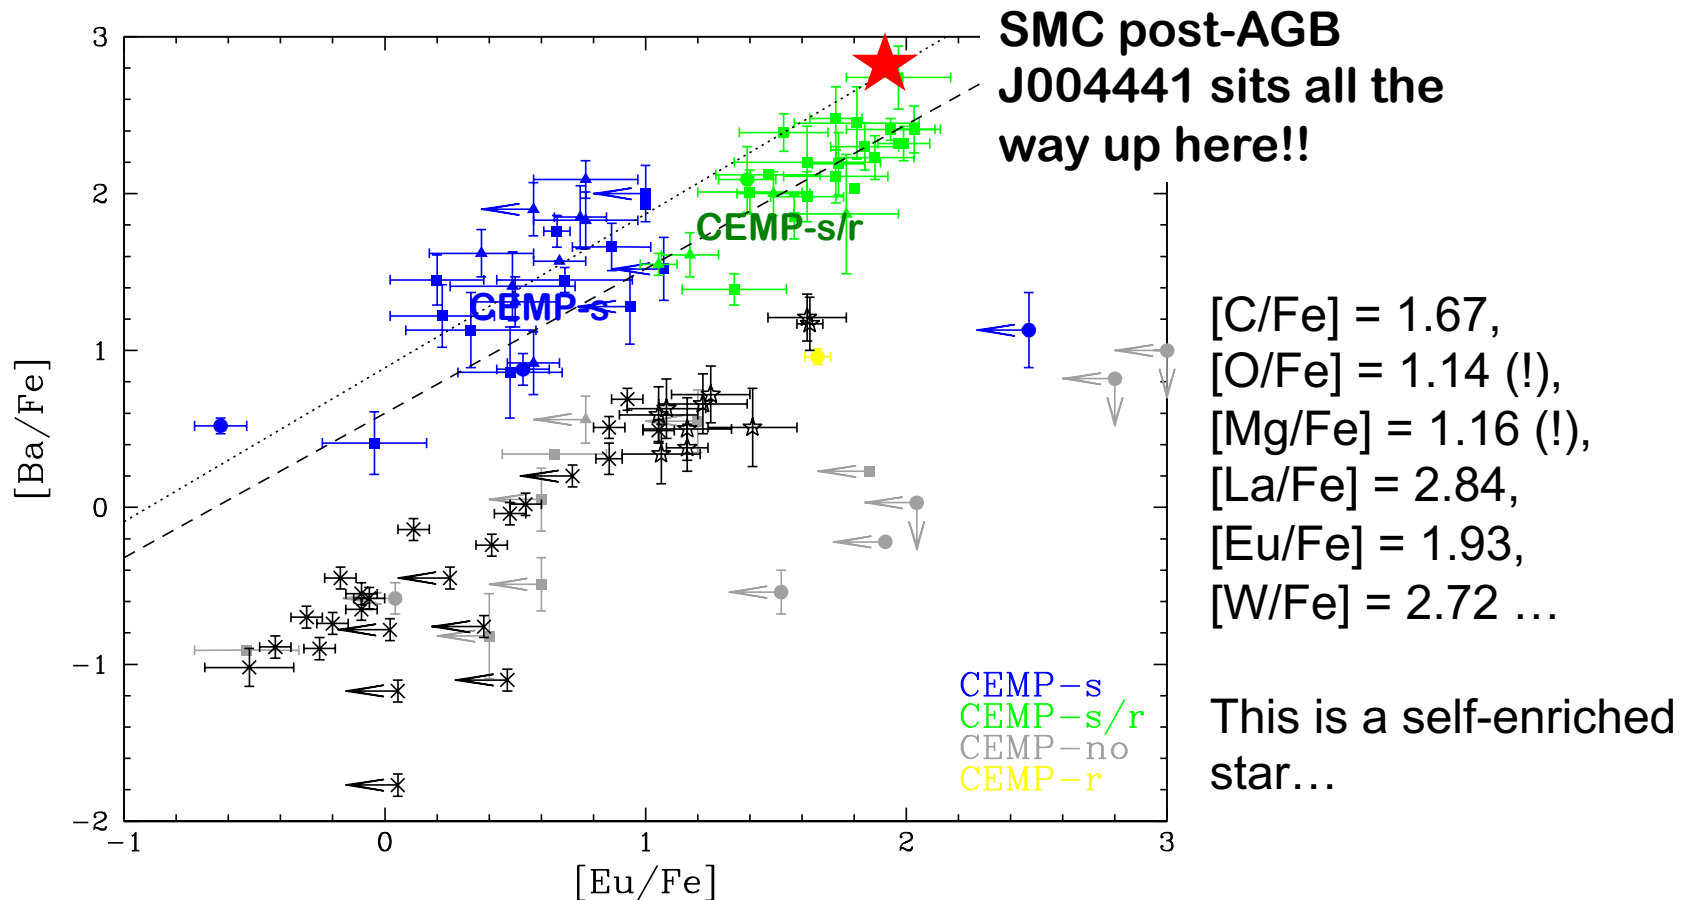

Puzzles:

- Low Pb is found in **ALL** stars with $[\text{Fe}/\text{H}] < -0.7$
- Can the low Pb be explained by variations in ^{13}C pocket sizes? (e.g., Trippella et al. 2016)
- Or is it an “i-process” (Lugaro et al. 2015)

Figure from
Kenneth De Smedt

CEMP post-AGB stars

- Where are they on the Ba/La-Eu diagram?

Using the data and classification of Masseron et al. (2010)

Where is the s-process made?

- When neutrons are released in the He-burning shell via (α, n) reactions. Where?
- Any star (it seems) where proton ingestions occur in a He-burning region
- This includes:
 1. AGB stars
 2. RGB stars undergoing core He-flash (e.g., Campbell)
 3. Massive stars (e.g., Banerjee)
- The s-process also occurs in (rotating) massive stars (e.g., talk by **Choplin**, and papers by Frischknecht, Pignatari)

Asymptotic Giant Branch Stars

Asymptotic Giant Branch stars:
($0.8 \lesssim M/M_{\text{sun}} \lesssim 8$)

- After core He-burning, the C-O core contracts and the star becomes a giant again
- Double-shell configuration
- He-burning shell is thermally unstable and flashes every $\sim 10^4$ years
- Rapid, episodic mass loss erodes the envelope

**Reviews by Karakas & Lattanzio
(2014)**

Production of heavy elements

- Heavy elements: heavier than iron (Fe)
- Most heavy nuclei are formed by neutron addition onto Fe-peak elements
- Two processes:
 - *r-process* (rapid neutron capture)
 - *s-process* (slow neutron capture)

Reviews by Busso, Gallino & Wasserburg (1999); Kaeppeler et al. (2011); Meyer (1994)

A close-up, slightly angled view of the periodic table of elements. The focus is on the transition metals and lanthanides. Visible elements include Re (75, 186.2), Os (76, 190.2), Ir (77, 192.2), Pt (78, 195.09), Au (79, 196.967), Rh (45, 102.905), Pd (46, 106.4), Ag (47, 107.868), Cd (48, 112.411), Cu (29, 63.546), Zn (30, 65.38), Ni (28, 58.707), Co (27, 58.933), Fe (26, 55.845), Mn (25, 54.938), Cr (24, 51.996), V (23, 50.9415), Ti (22, 47.867), Nb (41, 92.90638), Mo (42, 95.94), Sn (50, 118.710), Pb (82, 207.2), Bi (83, 208.9804), Po (84, 209), At (85, 210), Rn (86, 222), Fr (87, 223), Ra (88, 226), Ac (89, 227), Th (90, 232.0377), Pa (91, 231.036), U (92, 238.02891), Np (94, 237.0481732), Pu (94, 244), Am (95, 243), Cm (96, 247), Bk (97, 247), Cf (98, 251), Es (99, 252), Fm (100, 257), Md (101, 258), No (102, 259), Lr (103, 260), La (57, 138.90547), Ce (58, 140.12), Pr (59, 140.90765), Nd (60, 144.242), Pm (61, 144.91288), Sm (62, 150.36), Eu (63, 151.964), Gd (64, 157.25), Tb (65, 158.92535), Dy (66, 162.50), Ho (67, 164.93032), Er (68, 167.259), Tm (69, 168.9304), Yb (70, 173.054), Lu (71, 174.967), Hf (72, 178.49), Ta (73, 180.94788), W (74, 183.84), Re (75, 186.207), Os (76, 190.23), Ir (77, 192.22), Pt (78, 195.084), Au (79, 196.96657), Hg (80, 200.59), Tl (81, 204.38), Pb (82, 207.2), Bi (83, 208.9804), Po (84, 209), At (85, 210), Rn (86, 222), Fr (87, 223), Ra (88, 226), Ac (89, 227), Th (90, 232.0377), Pa (91, 231.036), U (92, 238.02891), Np (94, 237.0481732), Pu (94, 244), Am (95, 243), Cm (96, 247), Bk (97, 247), Cf (98, 251), Es (99, 252), Fm (100, 257), Md (101, 258), No (102, 259), Lr (103, 260).

Schematic AGB evolution

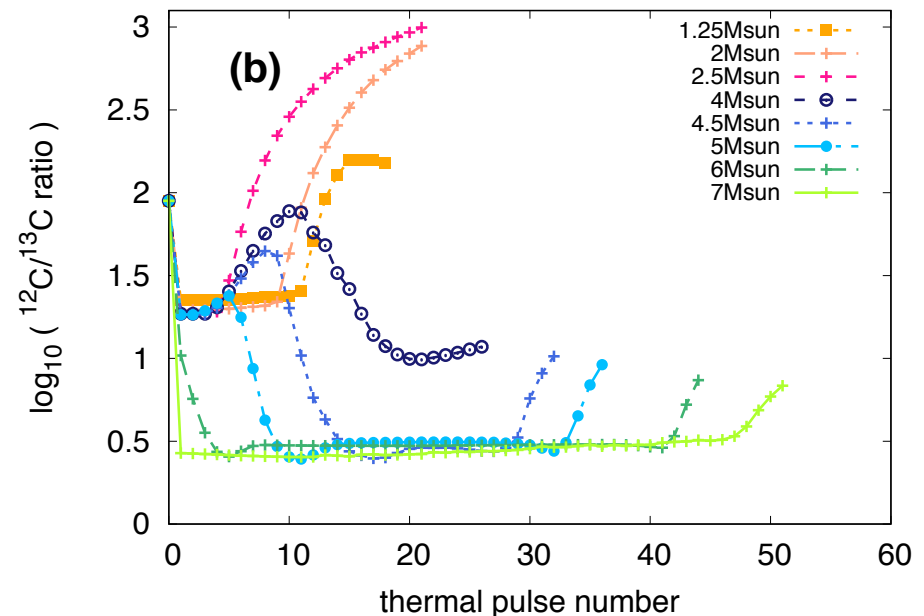

${}^4\text{He}$, ${}^{12}\text{C}$, s-process elements: Zr, Ba, ...

Nucleosynthesis

- **Low-mass:** ~ 0.9 to $2.5 M_{\text{sun}}$ for $[\text{Fe}/\text{H}] = -2.3 \rightarrow \text{CEMP}$
 - Third dredge-up: helium shell mixed into the envelope (e.g., ^{12}C , s-elements)
- **Intermediate-mass:** $M \gtrsim 3 M_{\text{sun}}$ for $[\text{Fe}/\text{H}] = -2.3 \rightarrow \text{NEMP}$
 - Hydrogen burning at base of convective envelope (e.g., ^{14}N)
 - Plus third dredge-up, which produces primary C and N

Models of $[\text{Fe}/\text{H}] = -0.7$ (Karakas et al. 2017, in prep)

The s-process: Effect of metallicity

FRUITY database: From Cristallo et al. (2015); also AGB models by Bisterzo et al. (2010) and NuGrid collaboration (e.g., Pignatari et al. 2016)

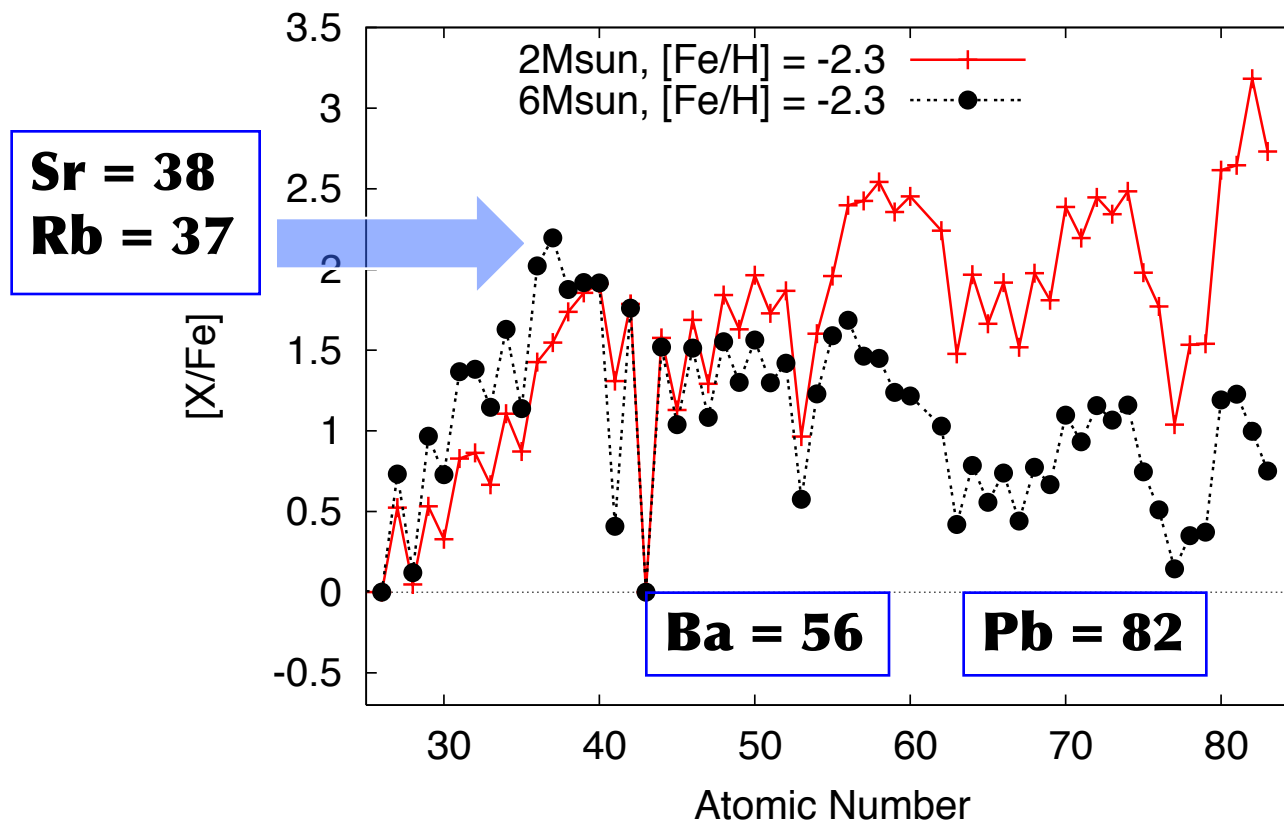

Pb ($Z=82$)

Z = proton number

The s-process: The effect of mass

- The s-process in a 6Msun, $Z = 0.0001$ AGB star produces copious Rb ($Z=37$) compared to Ba, Pb
- This is because it occurs at high neutron densities: $\sim 10^{13}$ n/cm³
- Yields for $[\text{Fe}/\text{H}] = -2.3$ are published in Lugaro, Karakas, et al. (2012) for $M = 1$ to 6Msun

Results: [Ba/Fe] versus [Eu/Fe]

Top panel: results of different masses, scaled solar initial composition
Lower panel: results of variations in the initial composition for the 2Msun Stromlo model

Summary:

- All models produce Ba and Eu with the prediction lines following the trend of the CEMP-s group
- AGB models do not produce the high [Eu/Fe] seen in the CEMP-s/r stars
- Increasing the initial [r/Fe] produces same final [Ba/Fe]
- Correlation between Ba and Eu of CEMP-s/r group **not** reproduced

Results: [Is/hs] versus [Mg/hs]

- Use “intrinsic” indicators, elemental ratios that only include elements produced in AGB stars
- Almost independent of model uncertainties (third dredge-up, mass loss, accretion, mixing processes)
- All our AGB models produce $[Is/hs] > -1$, similar to CEMP-s
- This is a basic fact about the s-process and comes from neutron-capture cross sections
- CEMP-s/r have the lowest $[Is/hs]$ and $[Mg/hs]$ values

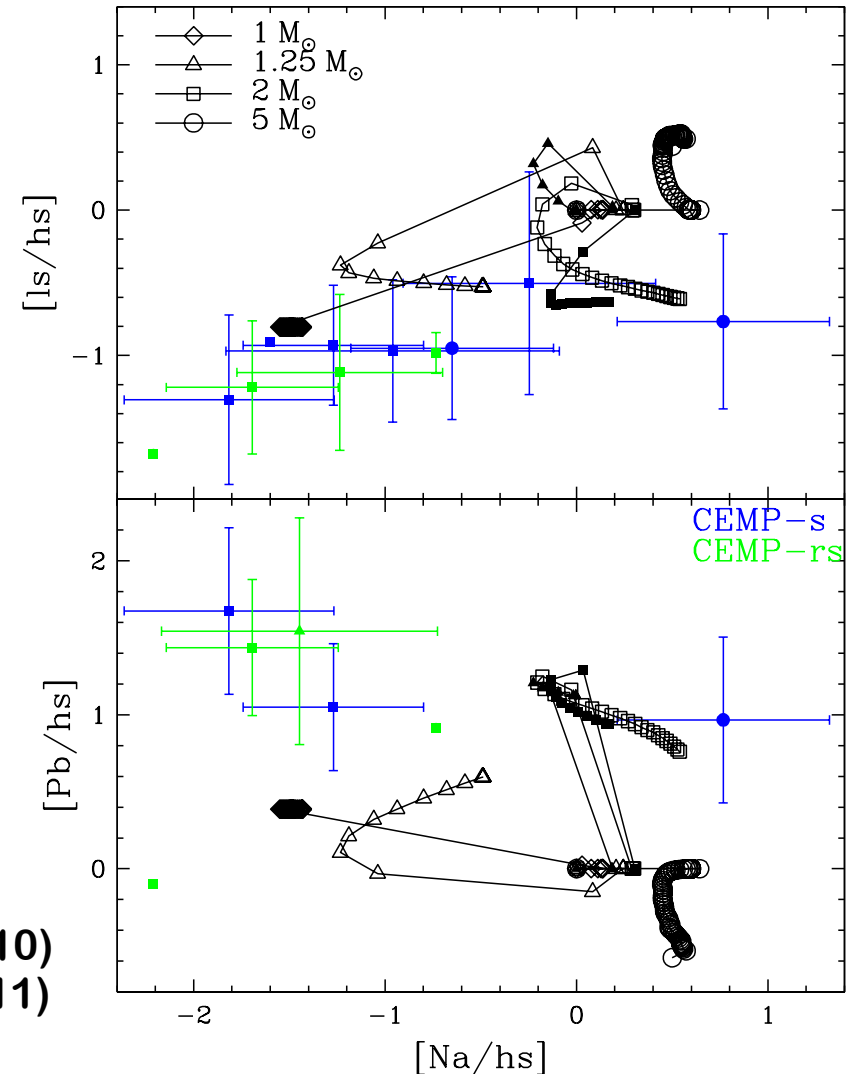

CEMP data from Masseron et al. (2010). Data for *Is* is taken from the SAGA database (Suda et al. 2008)

Is = light s-process elements (Sr, Y, Zr), hs = heavy s elements (Ba, La, Ce)

Results: Sodium and fluorine

- Models where ^{13}C burns radiatively provide a good match to the overall composition of CEMP-s stars in terms of their $[\text{Mg}/\text{hs}]$, $[\text{ls}/\text{hs}]$, and $[\text{Pb}/\text{hs}]$
- But produce too much Na and F with respect to the heavy s-process elements
- Could be related to the formation of the ^{13}C pocket (and ^{14}N pocket)
- Leads to Na production via $^{14}\text{N}(\alpha, \gamma)^{18}\text{O}(\alpha, \gamma)^{22}\text{Ne}$ in intershell then $^{22}\text{Ne}(\text{p}, \gamma)^{23}\text{Na}$

CEMP data from Masseron et al. (2010)
Data for Na from Lucatello et al. (2011)

The s-process in AGB stars

- How well do we really understand the operation of the s-process in AGB stars?
- This is a different question to the *accuracy of yields*, which depend on other modelling uncertainties (e.g., mass loss)

Neutron production is still poorly understood

Neutrons are produced ^{13}C pockets – we don't know how these form!

CEMP-s are mostly binaries

- But some of them appear single (Hansen et al. 2016)
- Are these non-binary CEMP-s formed by forming from material polluted by a massive star? *Talk by Choplin*
- *Answer, yes (?) at least for some (3/4) but not all*

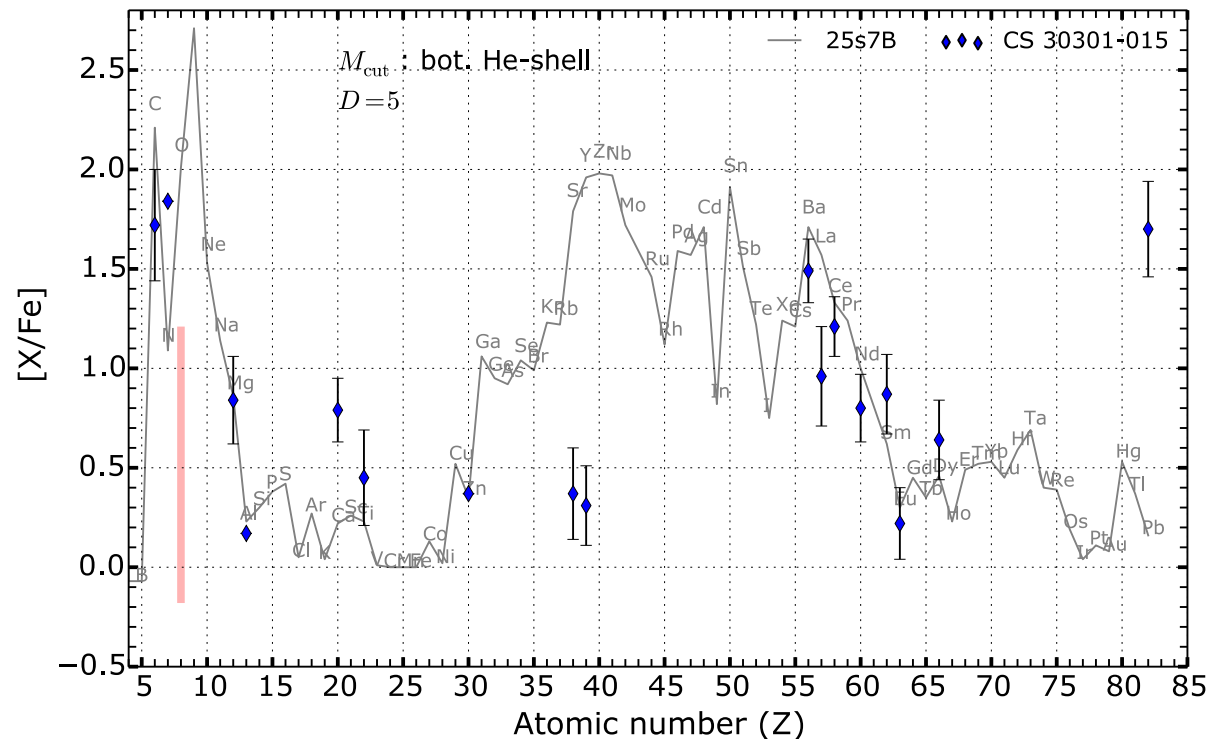

Figure from
Choplin et al. (2017)

Summary

- With available yields, we are now making quantitative chemical evolution predictions including heavy elements
- The new yields are timely, given the release of stellar abundance data from surveys for 100,000+ stars (e.g., GAIA-ESO survey; Galah in Australia, De Silva et al. 2015; K2 mission, e.g. Huber et al. 2016)
- Low-mass, low-metallicity AGB stars match composition of CEMP-s stars well but not CEMP-s/r (→ is it ‘i-process’?)
- New observations test our models of the s-process
- What is the origin of “Single” CEMP-s stars?
- What process is behind the post-AGB stars found in the Magellanic Clouds?
