

Visual Comparison of Events in Different Trackers

Andrew Olivier
DUNE ND Workshop
11/3/2017

Simulation Method

- 100 GENIE events from the DUNE near detector nominal flux
- Simulated all 100 events using edepsim in each of 4 geometries:
 - The KLOE straw tube tracker
 - The KLOE liquid argon tracker
 - Replaced KLOE STT with block of gaseous argon at about 10 atm
 - Replaced KLOE STT with block of Minerva's Scintillator

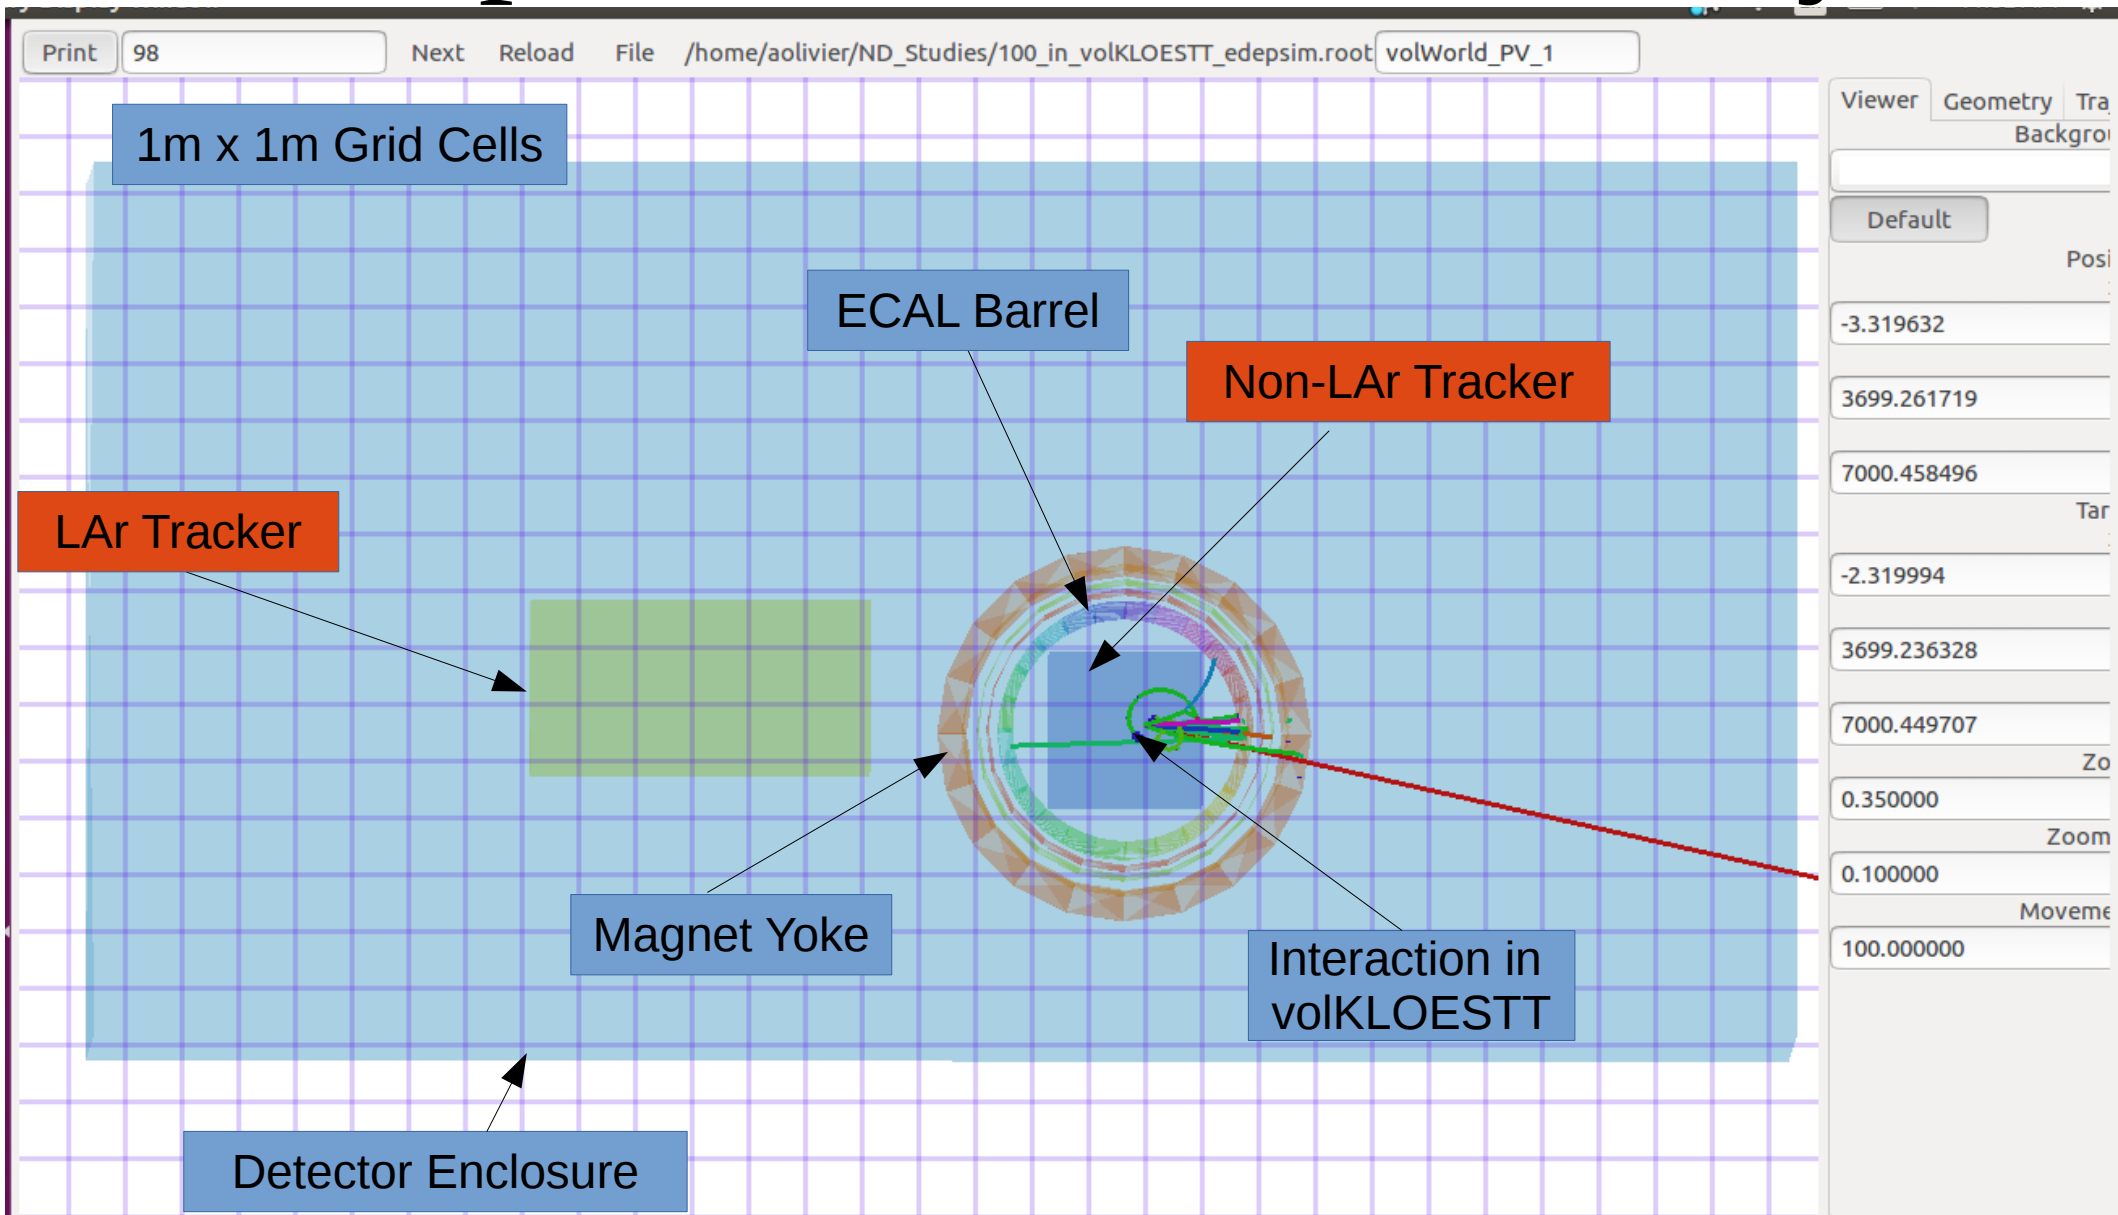

Visualization

- Developed an executable that reads edepsim's output files and draws:
 - Nodes from the ROOT geometry edepsim saved
 - Trajectory points from true particles
 - Mapped particle type to color
 - Linear interpolation between trajectory points. No fitting for B field.
 - Exiting trajectories are interpolated to the end of the sensitive volume.
 - True energy deposits
 - Color from $\log(dE/dx/density * A/Z)$ to show energy loss while getting same order of magnitude for all four trackers
 - Linear interpolation between start and end. No fitting for B field.
- All distances in mm and energies in MeV

Backup: Simulation Method Details

- Started with 100 GENIE events from the DUNE near detector nominal flux
- Simulated all 100 events using edepsim on my laptop in each of 4 geometries:
 - The KLOE geometry file's argon-filled straw tube tracker. Made volKLOESTT gevgen_fnal's target volume.
 - The KLOE geometry's liquid argon tracker which is not in a magnetic field. Transformed GENIE interaction records from volKLOESTT to volLArTracker. Can provide a ROOT script to do this given the geometry file GENIE used.
 - Replaced the KLOE STT with a block of the HP gaseous argon mix from dunendggd . Used GENIE interaction records from volKLOESTT.
 - Replaced the KLOE STT with a block of scintillator from Minerva's gdml file for the Inner Detector. Used GENIE interaction records from volKLOESTT.

Backup: Visualization Details

- Developed an application in c++ with a gtkmm 3.18 GUI that reads edepsim's ROOT output files and uses the opengl 3.3 core profile to draw:
 - Nodes from the ROOT geometry edepsim saved. Performs translations with TGeoMatrix
 - Color has no special meaning
 - Could be cut by material
 - Only first 7 levels of hierarchy included to reduce time to load each new file
 - Trajectory points from true particles
 - Mapped PDG code to color
 - Linear interpolation between trajectory points. Interpolate to end of sensitive volume for true trajectories that leave it. No fitting for B field
 - True energy deposits
 - Color from $\log(dE/dx)$ in MeV/cm. Same scale for each detector
 - Linear interpolation between start and end. Can only be in sensitive volume because of edepsim. No fitting for B field
 - Grids with distances from 1m x 1m to 1mm x 1mm for units in powers of 10.
 - Most plots show a 1dm x 1dm grid and a 1m x 1m grid.
- All distances in mm and energies in MeV

Backup: Software Details

- Built everything on ubuntu 16.04 LTS except gevgen_fnal, which I ran on dunegpvm02
- KLOE geometry file from dunendggd
- dunendggd depends on gegede
- gcc 5.4.0
- ROOT 6.09/01 built from source with GDML support and MINUIT 2 enabled for another project
- Geant 4.10.3 built from source
- edepsim from github built from source
- Gtkmm 3.18
- Opengl 3.3 core profile → no fixed function pipeline like glBegin().
