

# LAr hadronic containment Event rates vs. kinematics vs. detector size

Chris Marshall  
Lawrence Berkeley National Laboratory  
DUNE ND workshop  
6 November, 2017

# Containment, efficiency, event rates

- Simulate GENIE events in LAr with Geant4
- Separate large ( $\sim 7\text{M}$  event) sample into bins of  $E_\nu$  and elasticity  $1-y = E_\mu/E_\nu$
- For each event, ask: what is the extent of the hadronic shower in each direction?
- Or, for a given detector size (i.e.  $3\times 3\times 4\text{m}$ ): what is the fiducial volume for this event to be fully contained?
- From that, determine:
  - Efficiency for full containment in each bin
  - Expected event rates

# Event “extent” in each direction

- Event display in XZ plane, where color is hit energy in MeV (in 3x3mm voxyls)
- “Extent” is the minimum region that contains 95% of the visible (non-neutron) energy
- 20cm in Z and 40cm in X for this event
- Also a Y dimension which is used, but is not shown here

# Transverse extent in example bins

$2.5 < E_\nu < 3.0, 0.2 < 1-y < 0.3$

$2.5 < E_\nu < 3.0, 0.8 < 1-y < 0.9$

- Hadronic energy only
- Falling edge of flux peak, 2.5-3.0 GeV
- Left is very inelastic bin, right is very elastic

# Longitudinal extent examples

$2.5 < E_\nu < 3.0$ ,  $0.2 < 1-y < 0.3$

$2.5 < E_\nu < 3.0$ ,  $0.8 < 1-y < 0.9$

- Same bins as previous slide: left is very inelastic, right is mostly muon energy

# Transverse 99% containment

Transverse direction

Event distribution

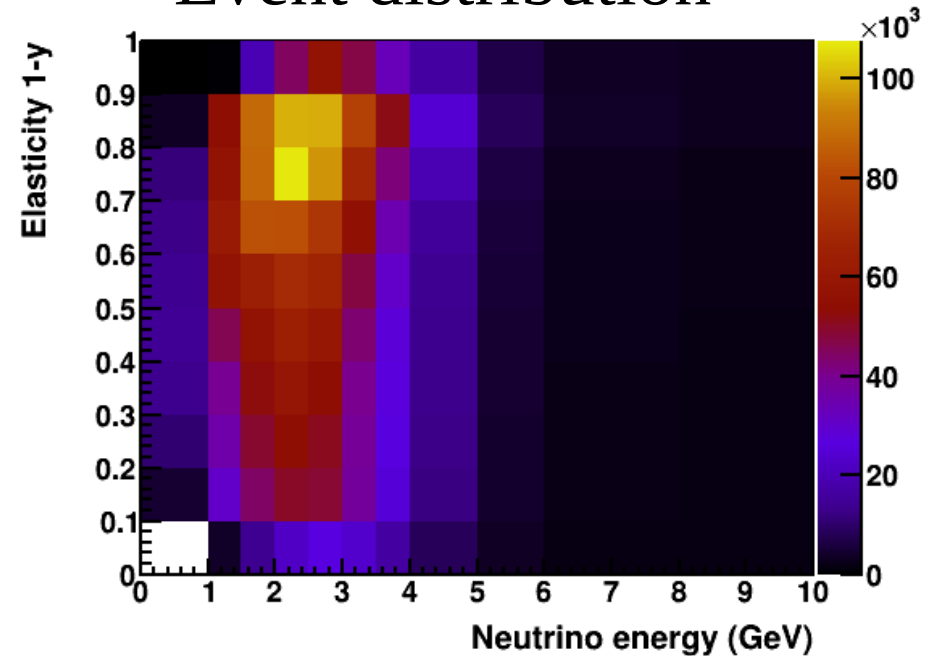

- Left: color of each bin is the minimum transverse size to contain 95% of hadronic energy in 99% of events in that bin
- Right: distribution of events

# Beam direction 99% containment

Transverse direction

Event distribution

- Left: color of each bin is the minimum longitudinal size to contain 95% of hadronic energy in 99% of events in that bin
- Right: distribution of events

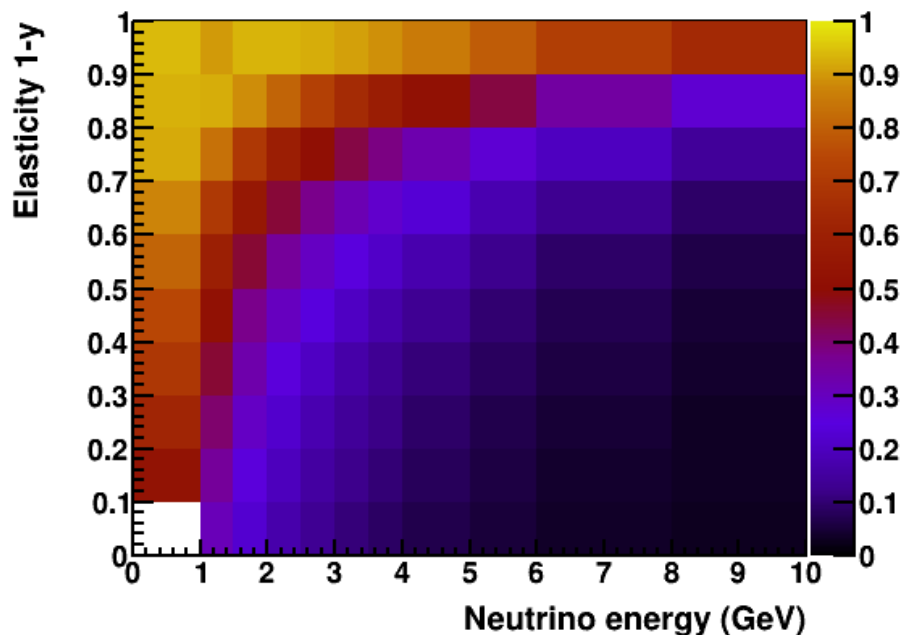

# Efficiencies

- Start with a fixed detector size, i.e. 3x3x4m
- Assume you need 50cm “empty” around an event to know that it is contained, so an event is “contained” if 95% of its hadronic energy is within the region with 50cm buffer around it, i.e. 2x2x3m FV
- Assume uniform distribution of vertices
- Determine efficiency in each kinematic bin
- Note: We don't expect this efficiency to be high for all kinematics. If a vertex is 50cm from the downstream edge of the detector and there is 2 GeV of hadronic energy, it's not likely to be contained

# Efficiencies for 95% hadronic containment with 50cm buffer

2x2x4

3x3x4

- 2x2x4m detector (left)
- 3x3x4m detector (right)

# Efficiencies for 95% hadronic containment with 50cm buffer

2x3x4

4x4x5

- 2x3x4m detector (left)
- 4x4x5m detector (right)

# Is 99% of a given bin enough?

$2.5 < E_\nu < 3.0$ ,  $0.2 < 1-y < 0.3$

- For very inelastic interactions, even near the flux peak, 99+% of events can be fully contained in a  $\sim 2 \times 2$  m transverse region
- It is worth investigating what the events with larger transverse extent are
- We may be missing some particular topology

# Event rates per year

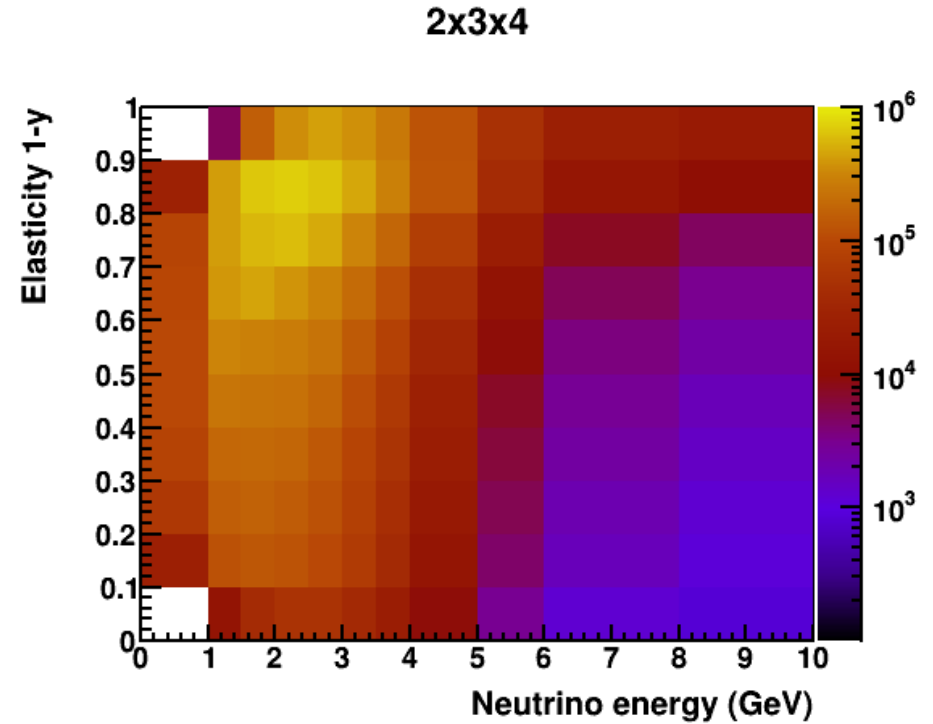

- Assuming 1MW beam,  $1.47E21$  POT
- Rates shown are per GeV per 0.1 bin of 1-y
  - Add up the column to get per GeV for all y
- Assumes you analyze a F.V. with 50cm buffer only, but accept only events which are fully contained inside the F.V.
- Rates are per 1 year, for whatever mass the detector has (varies due to different sizes)

# 2x2x4 detector

- $\sim 10^4$ - $10^5$  per bin in the peak
- 1000s events per bin at 5-8 GeV

# 2x3x4 detector

- $\sim \text{few} * 10^5$  per bin in the peak
- 1000s events per bin at 5-8 GeV

# 3x3x4 detector

- Millions of events per bin in the peak, with  $\sim 10^5$  for very inelastic events
- $\sim 10^3$ - $10^4$  per bin at 5-8 GeV

# 4x4x5 detector

- Quite a few events

# What about the muon?

- Previous slides all assumed the LAr was to contain hadrons only
  - Muon is reconstructed by downstream tracker or side detectors
- Briefly, let's look at what is required of the LAr TPC to contain high-angle muons

# Reminder: hadrons only

$2.5 < E_\nu < 3.0, 0.2 < 1-y < 0.3$

$2.5 < E_\nu < 3.0, 0.8 < 1-y < 0.9$

- Hadronic energy only
- Falling edge of flux peak, 2.5-3.0 GeV
- Left is very inelastic bin, right is very elastic

# Same bins, hadrons + muon

$2.5 < E_\nu < 3.0$ ,  $0.2 < 1-y < 0.3$

$2.5 < E_\nu < 3.0$ ,  $0.8 < 1-y < 0.9$

- 95% hadronic energy + 100% muon energy
- Falling edge of flux peak, 2.5-3.0 GeV
- Elastic events have forward muons (right), but inelastic events have big hadronic showers and high-angle muons (left)

# Including the muon

Minimum transverse for 99%

4x4x5

- Transverse dimension needs to be  $>5\text{m}$  if we need to reconstruct muons with only the LAr

# Conclusions

- Previous slides all assumed the LAr was to contain hadrons only
  - Muon is reconstructed by downstream tracker or side detectors
- Briefly, let's look at what is required of the LAr TPC to contain high-angle muons
