Unitary evolution on a quantum computer

Digital quantum computers (QC):

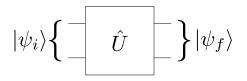

- \times Unitary gates $\sim e^{-it\hat{H}}$ of some \hat{H} .
- Want to simulate a lattice gauge theory (LGT)
- \times How to map its \hat{H} and its Hilbert space $\mathcal H$ on to QC?

Unitary evolution on a quantum computer

Digital quantum computers (QC):

- \times Unitary gates ~ $e^{-it\hat{H}}$ of some \hat{H} .
- $\times\,$ Want to simulate a lattice gauge theory (LGT)
- \times How to map its \hat{H} and its Hilbert space $\mathcal H$ on to QC?

Near-term QC architectures will have very limited capabilities

How to most wisely spend those qubits?

\times Arena for these questions is the Hamiltonian formalism of LGT.

Kogut-Susskind Hamiltonian:

D.B. Kaplan & J.R. Stryker (INT@UW)

Gauss's Law, U(1) & Duality (1806.08797)

Issues with standard formulation

 Must impose Gauss's law on kets [Kogut and Susskind 1975; Zohar et al. 2017]

• Most directions in \mathcal{H} unphysical.

- Danger of leaving \mathcal{H}_{phys} due to errors, noise
- If truncating states (by e.g. $|\mathcal{E}_{\ell}| \leq \Lambda$ in U(1)), makes awkward constraints around cutoff.

E fluctuations at weak coupling

Analogy to SHO: (electric field is momentum, gauge field is coordinate)

$$H_E = \frac{1}{2a_s} \sum_{\ell} \tilde{g}_t^2 \hat{\mathcal{E}}_{\ell}^2 \sim \frac{1}{2m} \hat{p}^2$$
$$H_B = \frac{1}{2a_s} \left[\frac{1}{\tilde{g}_s^2} \sum_{\boldsymbol{p}} \left(2 - \hat{P}_{\boldsymbol{p}} - \hat{P}_{\boldsymbol{p}}^{\dagger} \right) \right] \sim \frac{k}{2} \hat{x}^2$$

Read off

$$m \sim 1/\tilde{g}_t^2, \qquad k \sim 1/\tilde{g}_s^2$$

By dimensional analysis,

 $\langle \hat{p}^2 \rangle \propto \sqrt{mk} \sim \frac{1}{\tilde{g}_t \tilde{g}_s}, \qquad \langle \hat{x}^2 \rangle \propto \frac{1}{\sqrt{mk}} \sim \tilde{g}_t \tilde{g}_s$

Topological sectors

Original formulation (on periodic lattice) has many gauge-invariant states decoupled from $|\Omega\rangle$

- Topological Polyakov loops are gauge-invariant
- \times Define class representatives,

$$|\boldsymbol{\nu}\rangle \equiv \prod_{i=1}^{d} \left(\hat{W}(C_i) \right)^{\nu_i} |0\rangle , \quad \nu_i \in \mathbb{Z} .$$

with $\hat{W}(C_i)$ the product of oriented \hat{U}_{ℓ} 's along a closed loop C_i wrapping direction i.

 \times An H containing only elementary Wilson loops cannot cause transitions

Fully general state:

$$|\mathscr{A}\rangle_{\nu} = \prod_{p} \left(\hat{P}_{p} \right)^{\mathscr{A}_{p}} |\nu\rangle , \ \mathscr{A}_{p} \in \mathbb{Z}$$

LALLICE 18

Further details

Dual Hamiltonian with topology

Since ν 's don't talk to each other, we fix ν . We must adapt \mathcal{H} to get the right matrix elements:

$$\mathcal{H} \rightarrow \mathcal{H}^{\nu} = \mathcal{H}_{B} + \mathcal{H}_{E}^{\nu}, \qquad (\mathcal{H}_{B} \text{ unchanged})$$
$$\mathcal{H}_{E}^{\nu} = \frac{1}{2a_{s}} \sum_{\mathbf{n}^{\star}} \left[-\frac{\tilde{g}_{t}^{2}}{\xi^{2}} a_{s}^{2} \hat{\mathcal{U}}_{\mathbf{n}^{\star}}^{\dagger} \Delta \hat{\mathcal{U}}_{\mathbf{n}^{\star}} \right], \qquad (\mathbf{D} = 2)$$

Here we have generalized to a **covariant Laplacian** $\Delta = \sum_{i=1}^{2} D_{i}^{+} D_{i}^{-}$,

$$\begin{array}{lll} D_1^+ F_{\mathbf{n}^\star} &=& (\mathscr{W}_{\{\mathbf{n}^\star,\mathbf{n}^\star-\mathbf{e}_1\}}F_{\mathbf{n}^\star-\mathbf{e}_1} - F_{\mathbf{n}^\star})/a_s \ , \\ D_2^+ F_{\mathbf{n}^\star} &=& (\mathscr{W}_{\{\mathbf{n}^\star,\mathbf{n}^\star+\mathbf{e}_2\}}F_{\mathbf{n}^\star+\mathbf{e}_2} - F_{\mathbf{n}^\star})/a_s \ , \end{array}$$

involving the (dual lattice) connection

$$\mathscr{W}_{\ell^{\star}} = \begin{cases} e^{i\xi\nu_{i}}, & \text{if } \ell \in C_{i}; \\ 1, & \text{otherwise} \end{cases}$$
D.B. Kaplan & J.R. Stryker (INT@UW) Gauss's Law, U(1) & Duality (1806.08797) 2018-07-25 LATTICE 18 3

Dual Hamiltonian in d = 3 + 1

- For D = 3 spatial dimensions, $p \leftrightarrow \ell^*$ (rather than $p \leftrightarrow \mathbf{n}^*$).
 - \times We define $\hat{\mathscr{Q}}_{\ell^\star}$'s and $\hat{\mathscr{U}}_{\ell^\star}$'s on local **dual link Hilbert spaces** by direct analogy.
 - \succ Then

$$\hat{\mathscr{H}}_{\boldsymbol{\nu}} = \frac{1}{2a_s} \left[\sum_{\boldsymbol{\ell}^{\star}} \frac{1}{\tilde{g}_s^2} \left(2 - \hat{\mathscr{Q}}_{\boldsymbol{\ell}^{\star}} - \hat{\mathscr{Q}}_{\boldsymbol{\ell}^{\star}}^{\dagger} \right) + \frac{\tilde{g}_t^2}{\xi^2} \sum_{\boldsymbol{p}^{\star}} \left(2 - \left(\mathscr{W}_{\boldsymbol{p}^{\star}} \hat{\mathscr{P}}_{\boldsymbol{p}^{\star}} + \text{h.c.} \right) \right) \right] \quad (D = 3).$$

Dual plaquettes $\hat{\mathscr{P}}_{p^{\star}}$ are usual products of $\hat{\mathscr{U}}_{\ell^{\star}}$'s, and

$$\mathscr{W}_{\boldsymbol{p}^{\star}} = \begin{cases} e^{i\xi\nu_{i}}, & \text{if } \boldsymbol{\ell} \in C_{i} ; \\ 1, & \text{otherwise} . \end{cases}$$
