Motivations

Challenges in predicting nuclear structure and reactions,
e.g.,

- Exotic nuclei, FRIB
- Astrophysics, radiative capture
- Fusion energy, ITER and NIF

These propel development of theories with predictive power:

- Fundamental, unified *ab initio* nuclear theory for nuclear structure and reactions

Background

Existing methods, e.g.,

- No-core Shell Model with Continuum
- No-core Shell Model/Resonating Group Method
- Gamow Shell Model
- Harmonic Oscillator Representation of Scattering Equations
- Green's Function Approaches
- Nuclear Lattice Effective Field Theory
- Many others

However, these successful methods may be challenged to retain full quantal coherence of all relevant nuclear processes

We introduce the time-dependent Basis Function (tBF) Method

- *Ab initio* approach
- Non-perturbative
- Retains full quantal interference
- Enables snapshots of dynamics
- Supercomputing directly applicable

Idea of tBF Method

1. *Ab initio* structure calculation

$$H_0 |\beta_i\rangle = E_i |\beta_i\rangle$$

$$H_0 = T_{rel} + V$$

$$\{|\beta_1\rangle, |\beta_2\rangle, \dots, |\beta_n\rangle\}$$

2. Scattering problem

$$i \frac{d}{dt} |\Psi(t)\rangle = H(t) |\Psi(t)\rangle$$

$$H(t) = T_{rel} + V + V(t)$$

- Scattering state = time-dependent superposition of eigenstates
- Operators become **matrices** in eigen-basis representation

1. Solve for the “target” system’s eigen-basis via *ab initio* calculation
2. Define the scattering state within this eigen-basis and evaluate $H(t)$ in this basis
3. Solve the equation of motion in this eigen-basis

Ab initio Structure Calculation of Deuteron

Hamiltonian of the deuteron

$$H_{\text{rel}} = T_{\text{rel}} + V_{\text{NN}}$$

with

- Intrinsic kinetic energy

$$T_{\text{rel}} = \frac{p_{\text{rel}}^2}{2m}$$

- Realistic inter-nucleon interaction

$$V_{\text{NN}}$$

3DHO Basis for NN Nuclear Structure Calculation

- Nuclear interaction conserves total angular momentum $\vec{J} = \vec{l} + \vec{S}$

$$|\beta_i\rangle \rightarrow |\{SJM_J T_z\}_i\rangle = \sum_{n,l} a_{nl}^i |nlSJM_J T_z\rangle$$

- Excitation quanta for basis space truncation:

$$N = 2n + l$$

- 3DHO basis wave function in coordinate space

$$\langle \vec{r} | nlSJM \rangle = R_{nl}(r) \sum_{m_l m_s} (l m_l S m_s | JM) Y_{l m_l}(\Omega_{\hat{r}}) \chi_{S m_s}$$

$$R_{nl}(r) = \sqrt{\frac{2n!}{r_0^3 \Gamma(n + l + \frac{3}{2})}} \left(\frac{r}{r_0}\right)^l \exp\left[-\frac{r^2}{2r_0^2}\right] L_n^{l+\frac{1}{2}}\left(\frac{r^2}{r_0^2}\right)$$

- Why 3DHO basis?
 - Respects the symmetries of the nuclear system
 - e.g., rotational and translational symmetries
 - The center of mass motion can be easily removed

SP16 interaction adopted for the initial application

Constructed by J -matrix inverse scattering theory

Reproduces NN scattering data

“16” means the interaction is fitted to reproduce some of the properties for ^{16}O

Reproduces selected properties of light nuclei

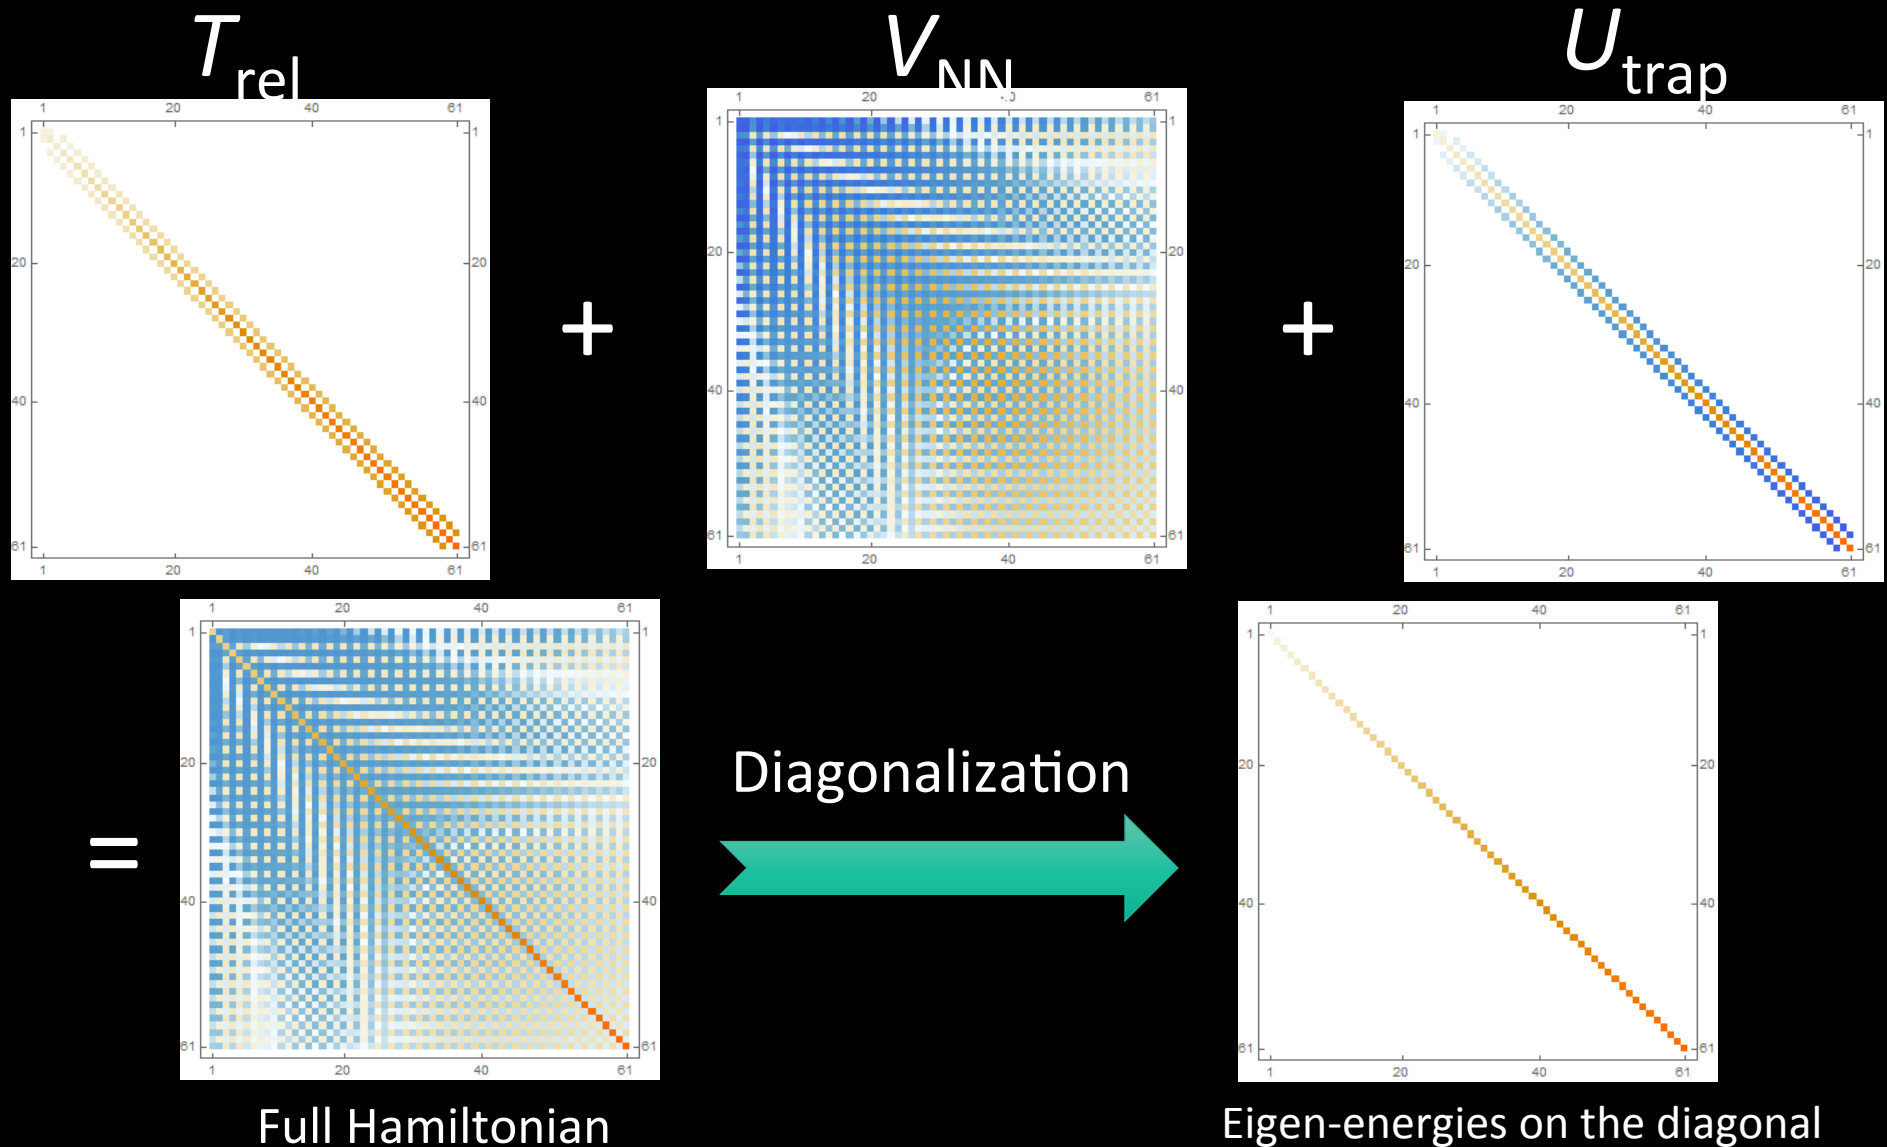

- e.g., ^2H , ^3H , ^4He

Includes two-nucleon (NN) interaction only

Non-local interaction

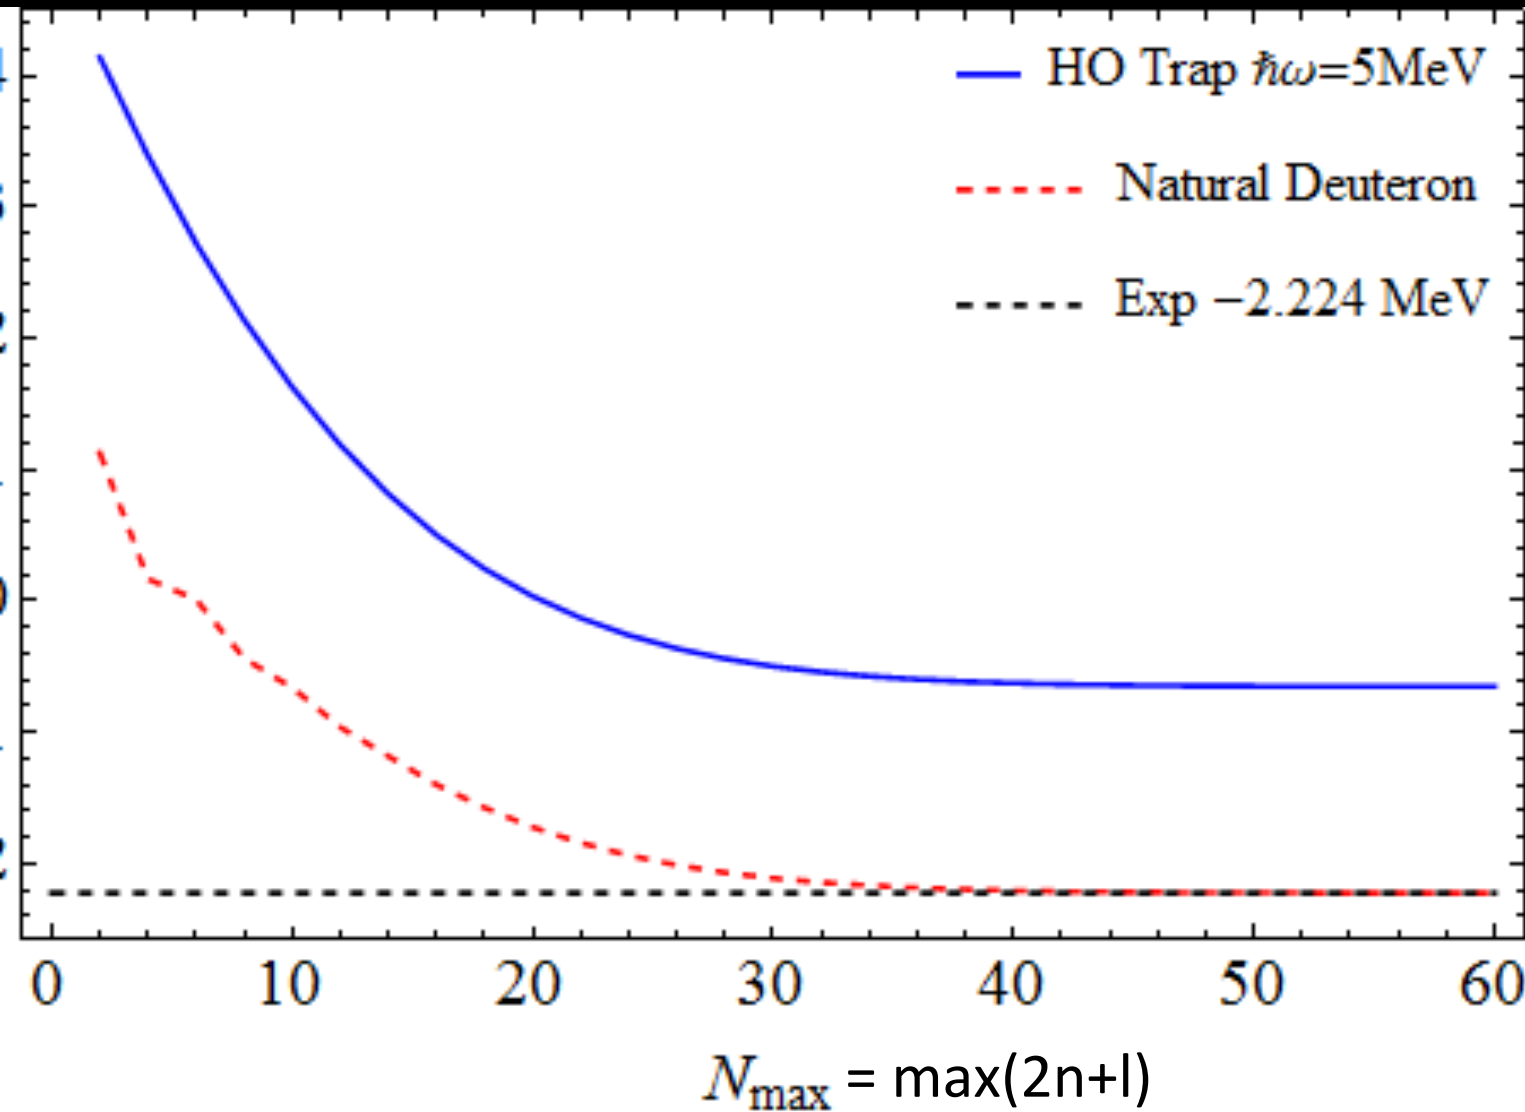

The interaction in 3DHO representation (matrix elements)

simplify the “continuum” => add a HO confining interaction
Hamiltonian for Quasi-deuteron in 3DHO Representation

Results:

Ground State Energies for Natural and Quasi-Deuteron

- $N_{\text{max}}=60$;
- Basis strength=5
- As the basis space increases in dimension, the theoretical ground state energy of the deuteron converges to the experimental value.

Time-Dependent Schrödinger Equation

Time-dependent full Hamiltonian

$$H(t) = H_0 + V_{\text{int}}(t)$$

Equation of motion

- Schrödinger picture

$$i \frac{\partial}{\partial t} |\psi; t\rangle = H(t) |\psi; t\rangle$$

- Interaction picture

$$i \frac{\partial}{\partial t} |\psi; t\rangle_I = e^{iH_0 t} V_{\text{int}}(t) e^{-iH_0 t} |\psi; t\rangle_I \equiv V_I(t) |\psi; t\rangle_I$$

Solve Time-dependent Schrödinger Equation

Equation of motion in interaction picture

$$i \frac{\partial}{\partial t} |\psi; t\rangle_I = V_I(t) |\psi; t\rangle_I$$

Formal solution

$$\begin{aligned} |\psi; t\rangle_I &= U_I(t; t_0) |\psi; t_0\rangle_I \\ U_I(t; t_0) &= \hat{T} \left\{ \exp \left[-i \int_{t_0}^t V_I(t') dt' \right] \right\} \end{aligned}$$

Transition Amplitudes of States

With the basis representation

$$H_0 |\beta_i\rangle = E_i |\beta_i\rangle$$

$$\{|\beta_1\rangle, |\beta_2\rangle, \dots, |\beta_n\rangle\}$$

the state vector for the system under scattering becomes

$$|\psi; t\rangle_I = \sum_{j=1}^n A_j^I(t) |\beta_j\rangle$$

$$|\psi; t_0\rangle_I \equiv |\beta_i\rangle$$

where the transition amplitude is

$$A_{i \rightarrow j}^I(t) \equiv A_j^I(t) = \langle \beta_j | U_I(t; t_0) | \beta_i \rangle$$

Numerical Method 1: Euler Method

Direct evaluation of the time-evolution operator

$$U_I(t; t_0) = T \exp \left[-i \int_{t_0}^t V_I(t) dt \right]$$

with

$$T \exp \left[-i \int_{t_0}^t V_I(t) dt \right] \xrightarrow{\sum \delta t} \left[1 - iV_I(t_n)\delta t + O(\delta t^2) \right] \left[1 - iV_I(t_{n-1})\delta t + O(\delta t^2) \right] \cdots \left[1 - iV_I(t_1)\delta t + O(\delta t^2) \right]$$

- Fast in calculation
- Accurate up to $(\delta t)^2$
- Hence poor numerical stability

Numerical Method 2: Multi-Step Differencing

Multi-step differencing (MSD2) for the evolution:

$$|\psi; t + \delta t\rangle_I = e^{-iV_I(t)\delta t}|\psi; t\rangle_I = (1 - iV_I(t)\delta t + O(iV_I(t)\delta t)^2)|\psi; t\rangle_I$$

$$|\psi; t - \delta t\rangle_I = e^{iV_I(t)\delta t}|\psi; t\rangle_I = (1 + iV_I(t)\delta t + O(iV_I(t)\delta t)^2)|\psi; t\rangle_I$$

$$|\psi; t + \delta t\rangle_I = |\psi; t - \delta t\rangle_I - 2iV_I(t)\delta t|\psi; t\rangle_I + O(iV_I(t)\delta t)^3|\psi; t\rangle_I$$

- MSD is an explicit method – it does not evaluate matrix inversions
- MSD2 is accurate up to $(\delta t)^3$
- MSD4 is accurate up to $(\delta t)^4$, however less efficient
- We employ MSD2 for better numerical stability and efficiency

For Comparison: First-Order Perturbation Theory

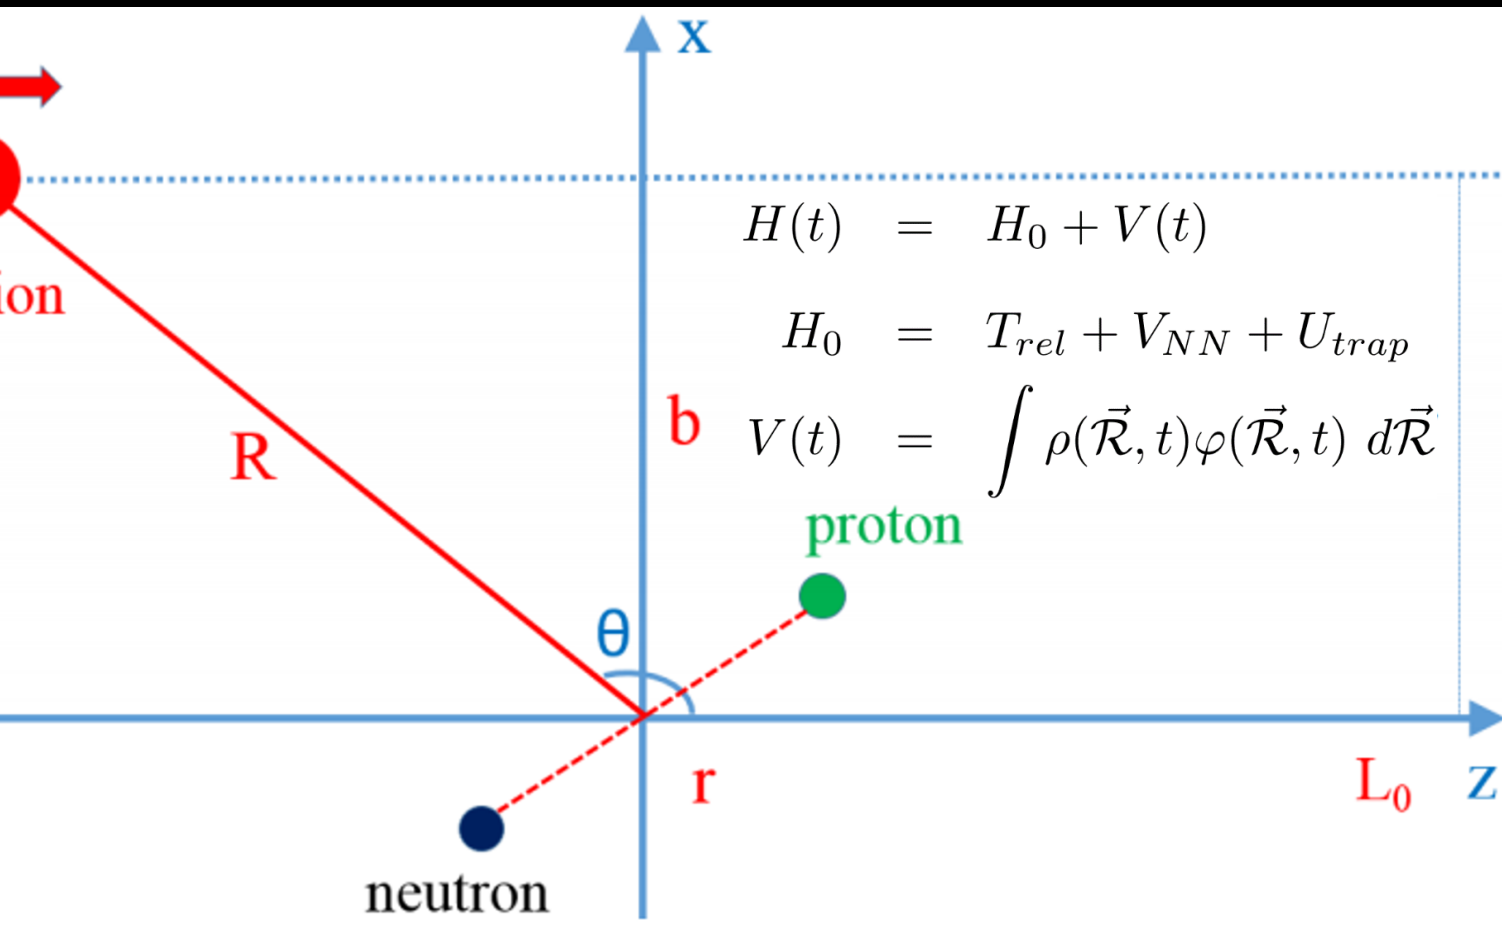

$$\begin{aligned} |\psi; t\rangle_I &= T \exp \left[-i \int_{t_0}^t V_I(t) dt \right] |\psi; t_0\rangle_I \\ &\rightarrow \left[1 - i V_I(t_n) \delta t \right] \left[1 - i V_I(t_{n-1}) \delta t \right] \cdots \left[1 - i V_I(t_1) \delta t \right] |\psi; t_0\rangle_I \\ &\rightarrow \left[1 - i \delta t \left(V_I(t_n) + V_I(t_{n-1}) + \cdots + V_I(t_1) \right) \right] |\psi; t_0\rangle_I \end{aligned}$$

Purposes for this comparison

- tBF method is non-perturbative
- tBF method evaluates all the higher-order effects

First Model Problem: Coulomb Excitation of Deuterium System by Peripheral Scattering with Heavy Ion

Setup: Coulomb Excitation of Deuterium System

H_0 : target Hamiltonian

φ : Coulomb field of heavy ion

ρ : Charge density distribution of deuteron

Treatment of time-varying Coulomb field

In the basis representation, the operator for the Coulomb interaction becomes a matrix

We take a multipole decomposition for the Coulomb field and keep only the E1 multipole component

K. Alder et al., Rev. Mod. Phys. 28, 432 (1956)

$$\langle \beta_j | V_I(t) | \beta_k \rangle = \frac{4\pi}{3} Z e^2 e^{i(E_j - E_k)t} \sum_{\mu} \frac{Y_{1\mu}^*(\Omega_{\hat{R}})}{|R(t)|^2} \langle \beta_j | \frac{r}{2} Y_{1\mu}(\Omega_{\hat{r}}) | \beta_k \rangle$$

E1 transition between bases

E1 Matrix Element in Basis Representation

E1 transition matrix element in the basis representation is evaluated by

- Basis functions from the *ab initio* structure calculation

$$|\beta_i\rangle \rightarrow |\{SJM_J T_z\}_i\rangle = \sum_{n,l} a_{nl}^i |nlSJM_J T_z\rangle$$

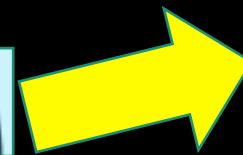

- And the analytic form of the E1 operator in 3DHO representation

$$\begin{aligned} & \langle n_j l_j S_j J_j M_j | \frac{r}{2} Y_{1\mu}(\hat{r}) | n_k l_k S_k J_k M_k \rangle \\ &= \sqrt{\frac{1}{4m\Omega}} \sum_{m_{l_j} m_{s_j}} \sum_{m_{l_k} m_{s_k}} \delta_{S_j S_k} \delta_{m_{s_j} m_{s_k}} (l_j m_{l_j} S_j m_{s_j} | J_j M_j) (l_k m_{l_k} S_k m_{s_k} | J_k M_k) \\ & \times (-1)^{m_{l_j}} \sqrt{\frac{3(2l_j + 1)(2l_k + 1)}{4\pi}} \begin{pmatrix} l_j & 1 & l_k \\ -m_{l_j} & \mu & m_{l_k} \end{pmatrix} \begin{pmatrix} l_j & 1 & l_k \\ 0 & 0 & 0 \end{pmatrix} \\ & \times \begin{cases} \sqrt{n_j + l_j + \frac{3}{2}} \delta_{n_j n_k} - \sqrt{n_j} \delta_{n_j, n_k + 1} & \text{for } l_k = l_j + 1 \\ \sqrt{n_k + l_k + \frac{3}{2}} \delta_{n_j n_k} - \sqrt{n_k} \delta_{n_k, n_j + 1} & \text{for } l_j = l_k + 1 \\ 0 & \text{else} \end{cases} \end{aligned}$$

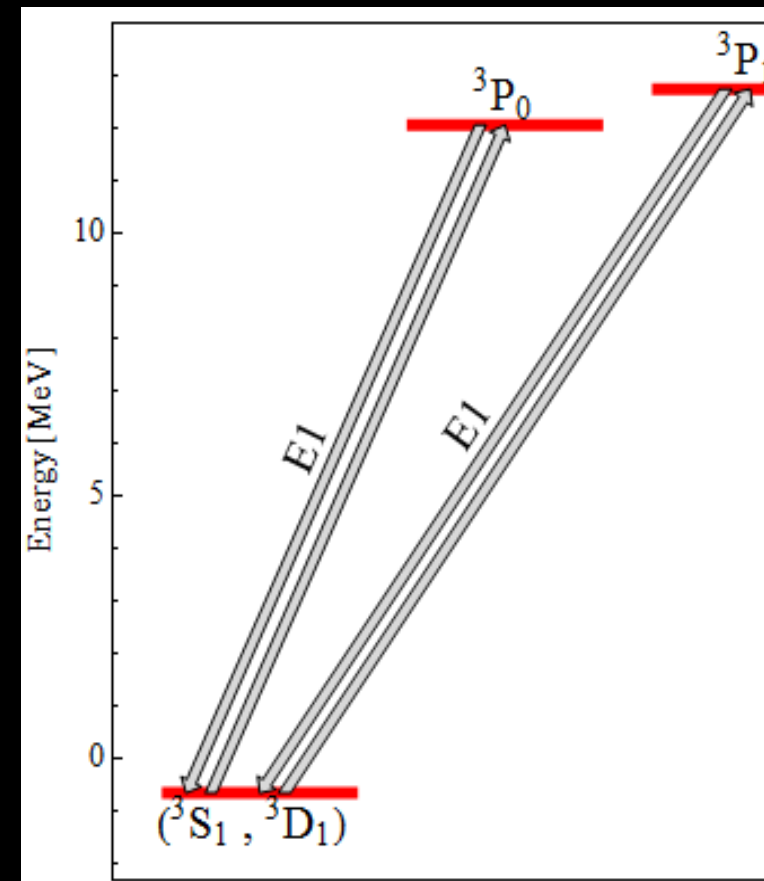

Basis Set for Deuteron in Current Calculation

7 basis states are solved via *ab initio* method

$(^3S_1, ^3D_1)$	$M = -1$	-0.65289 MeV
$(^3S_1, ^3D_1)$	$M = 0$	-0.65289 MeV

3P_1	$M = -1$	12.7585 MeV
3P_1	$M = 0$	12.7585 MeV
3P_1	$M = +1$	12.7585 MeV

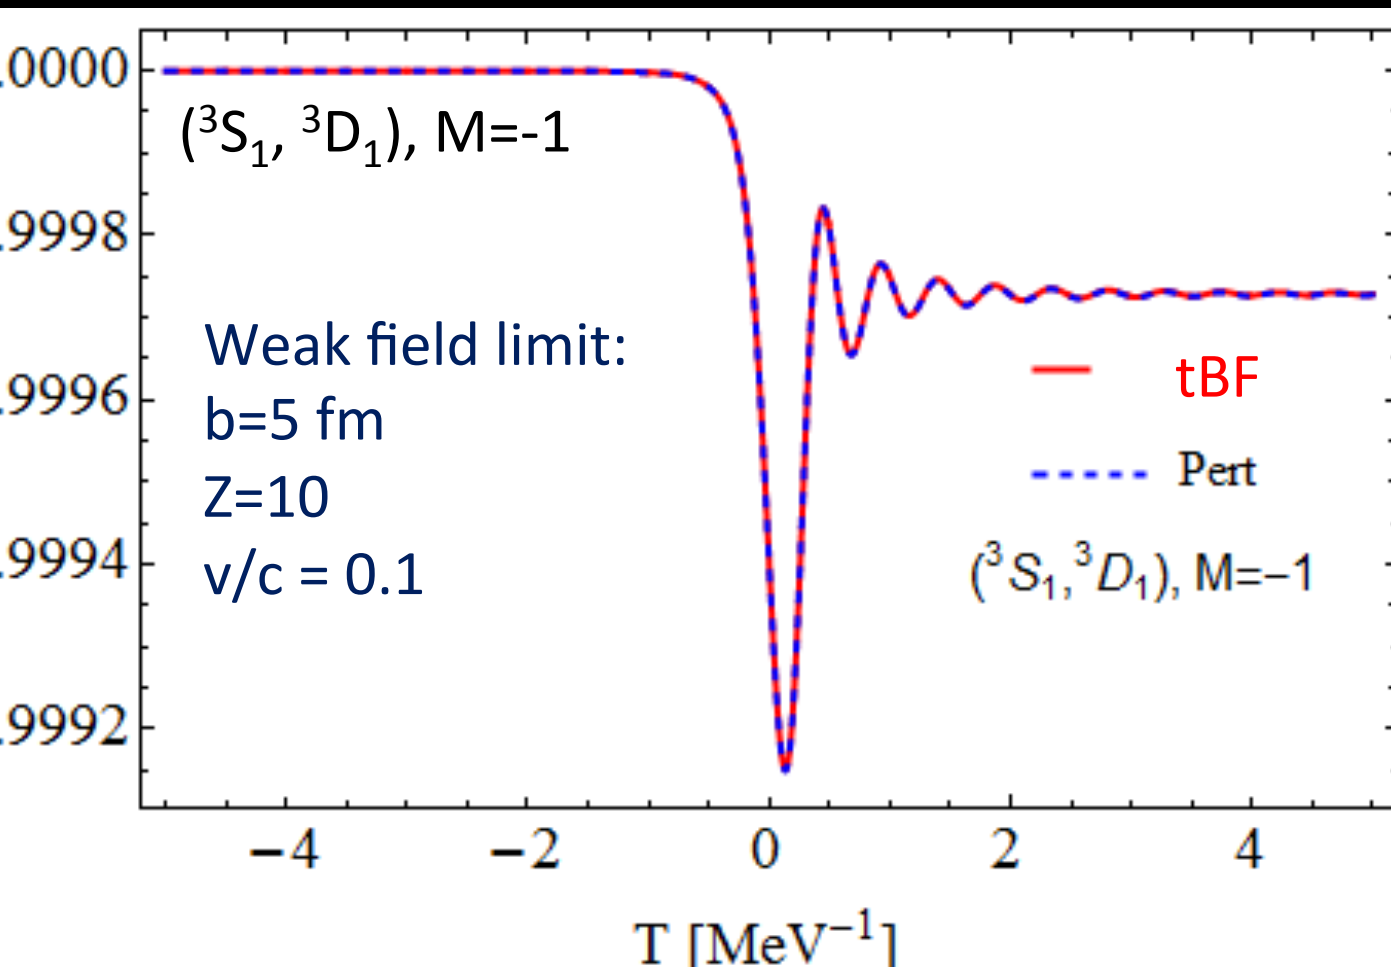

- Initial state
- Polarization antiparallel to z-axis
- E1 radiative transitions

NTSE proceeding, Weijie Du et al. 2017

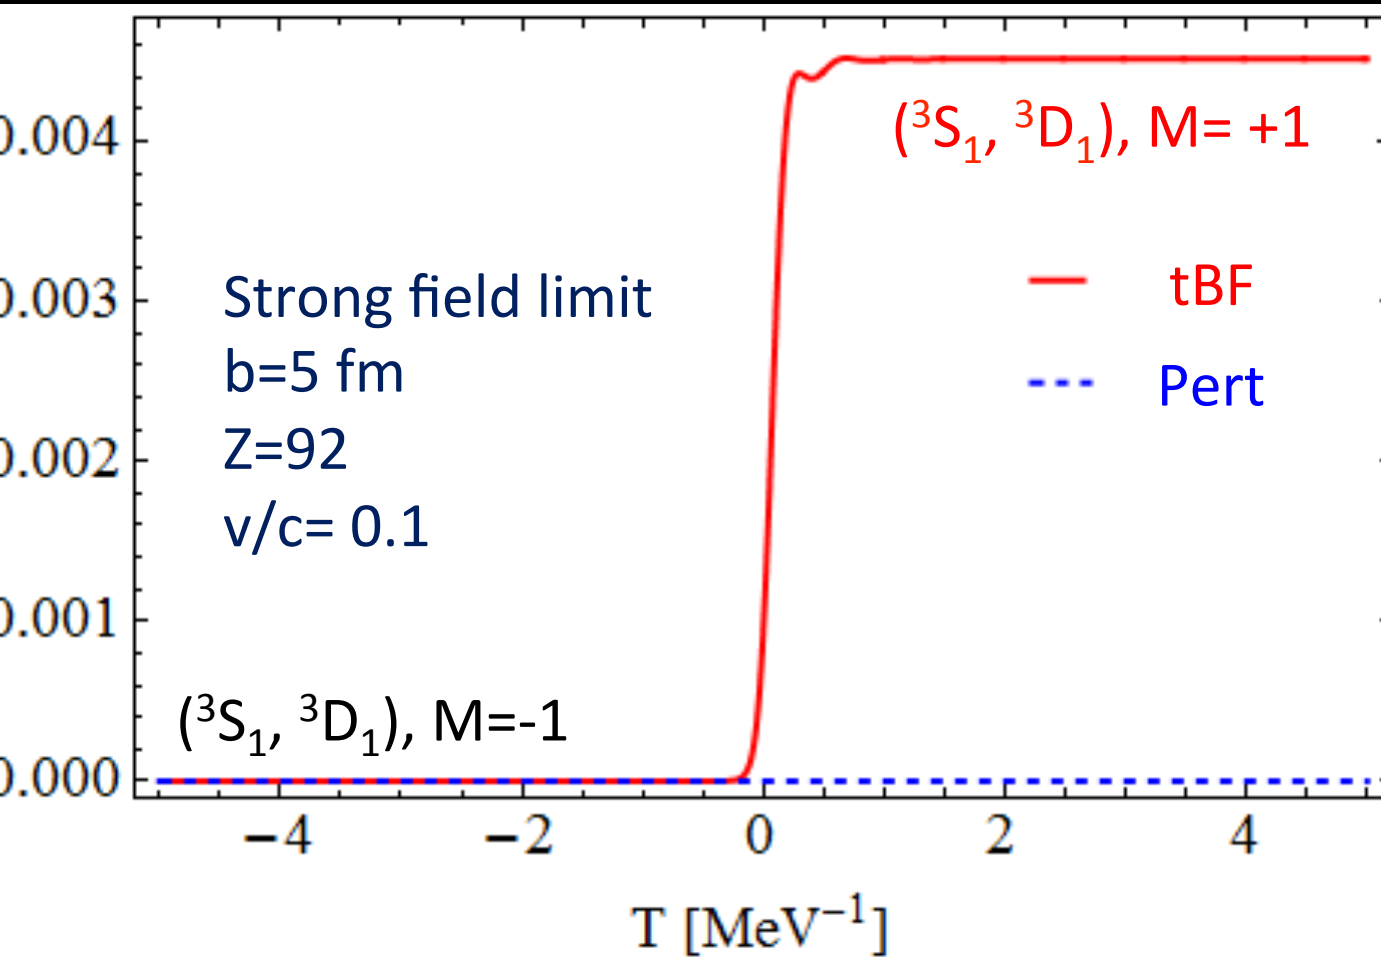

Transition Probabilities

Validity:

When the Coulomb field is weak, tBF method matches with first order perturbation theory

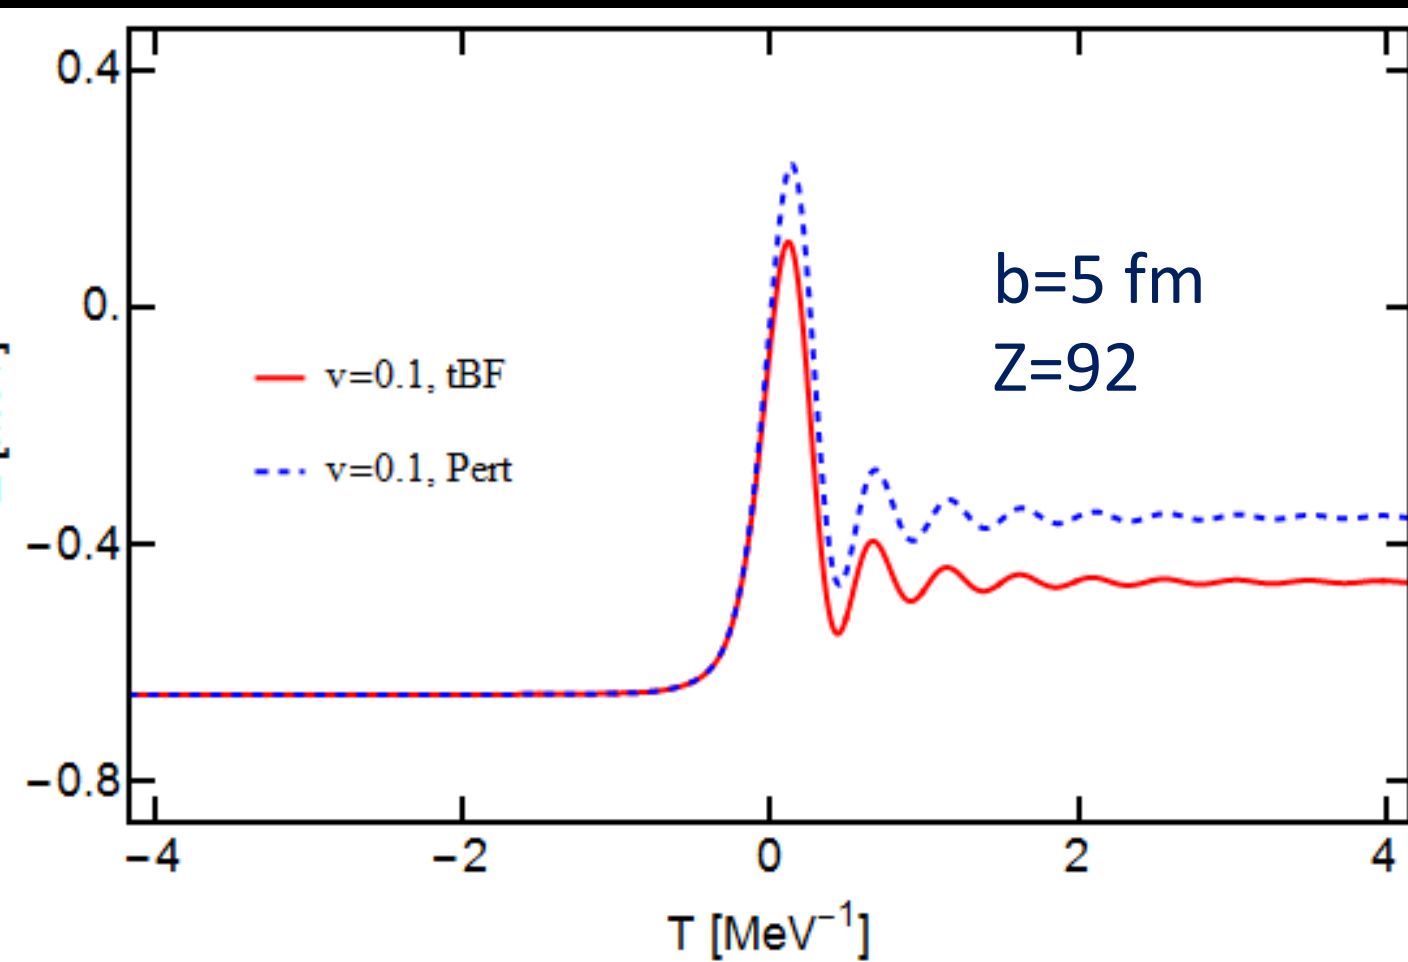

Higher-Order Effects

Forbidden transition

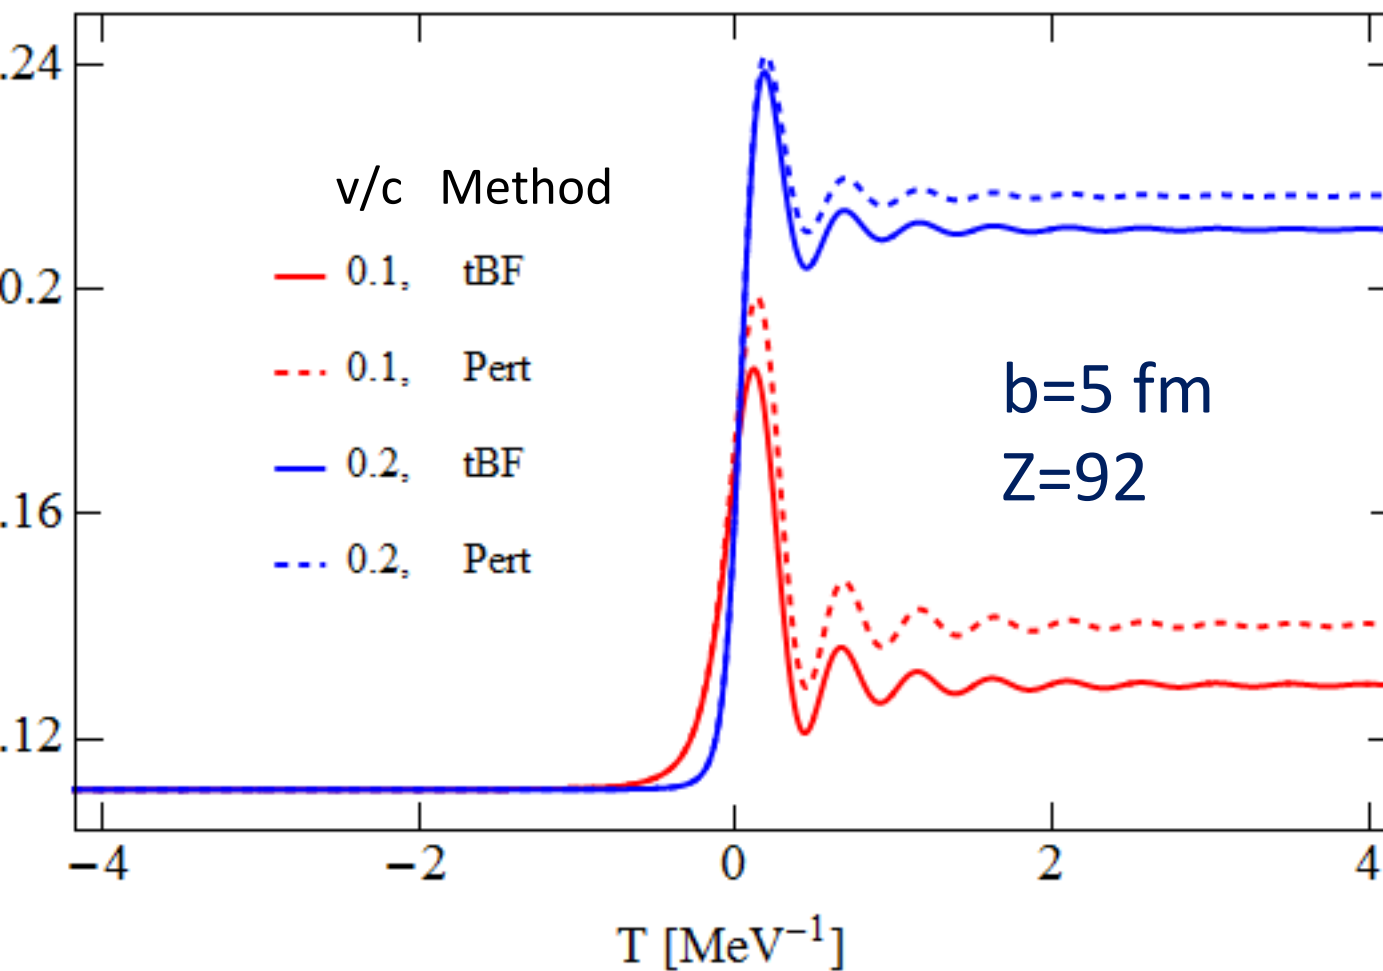

- Revealed by non-perturbative tBF

Excitation of Intrinsic Energy

- Observables as functions of time
- Quantum fluctuations are taken care at the amplitude level

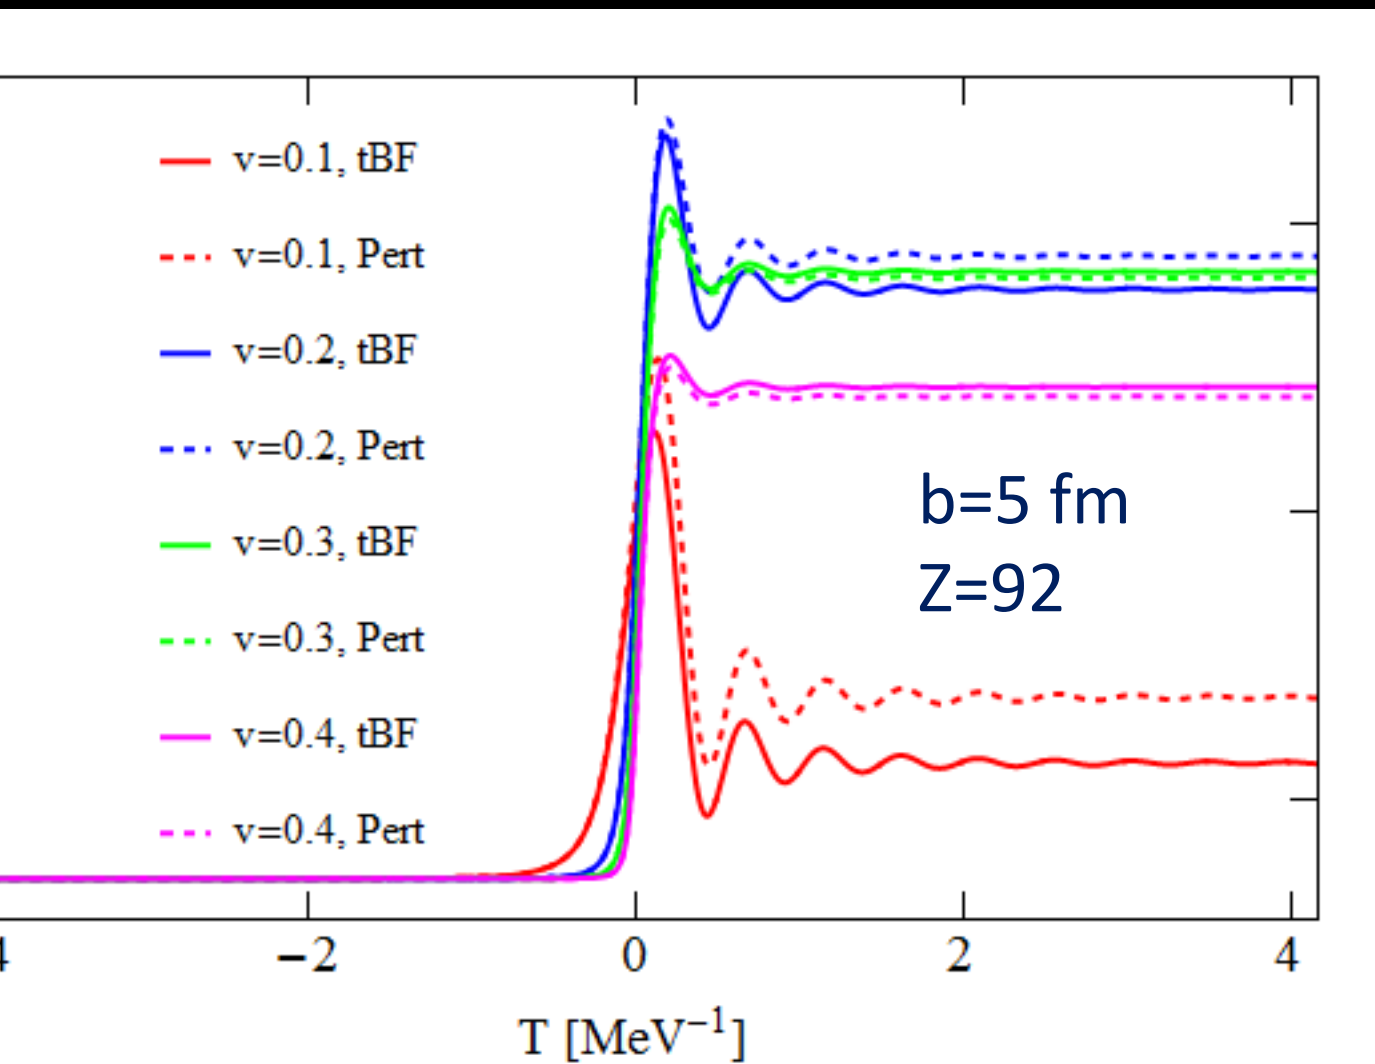

Excitation of Orbital Angular Momentum

Observable's
dependence on

- time
- incident spe

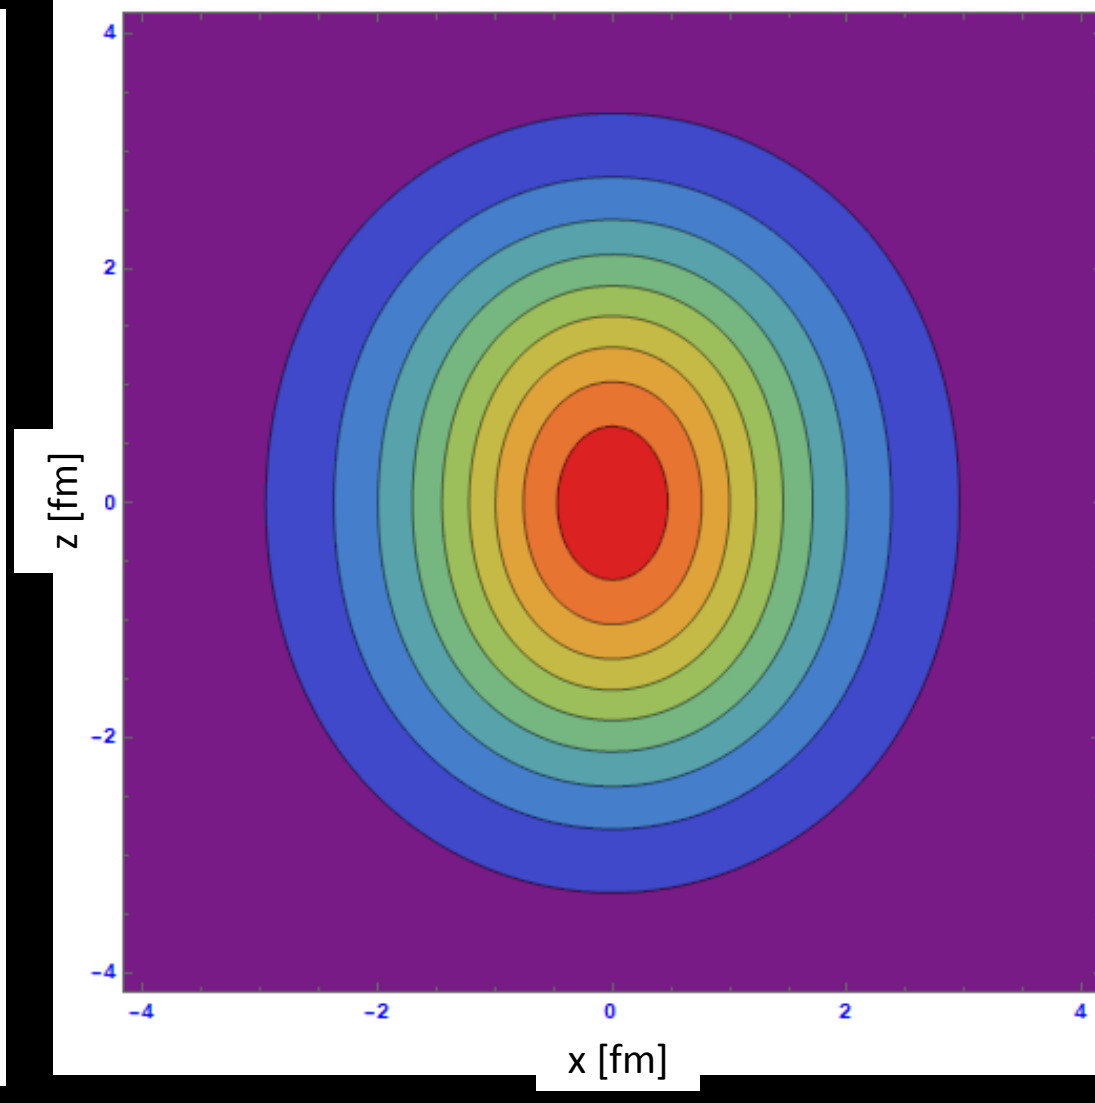

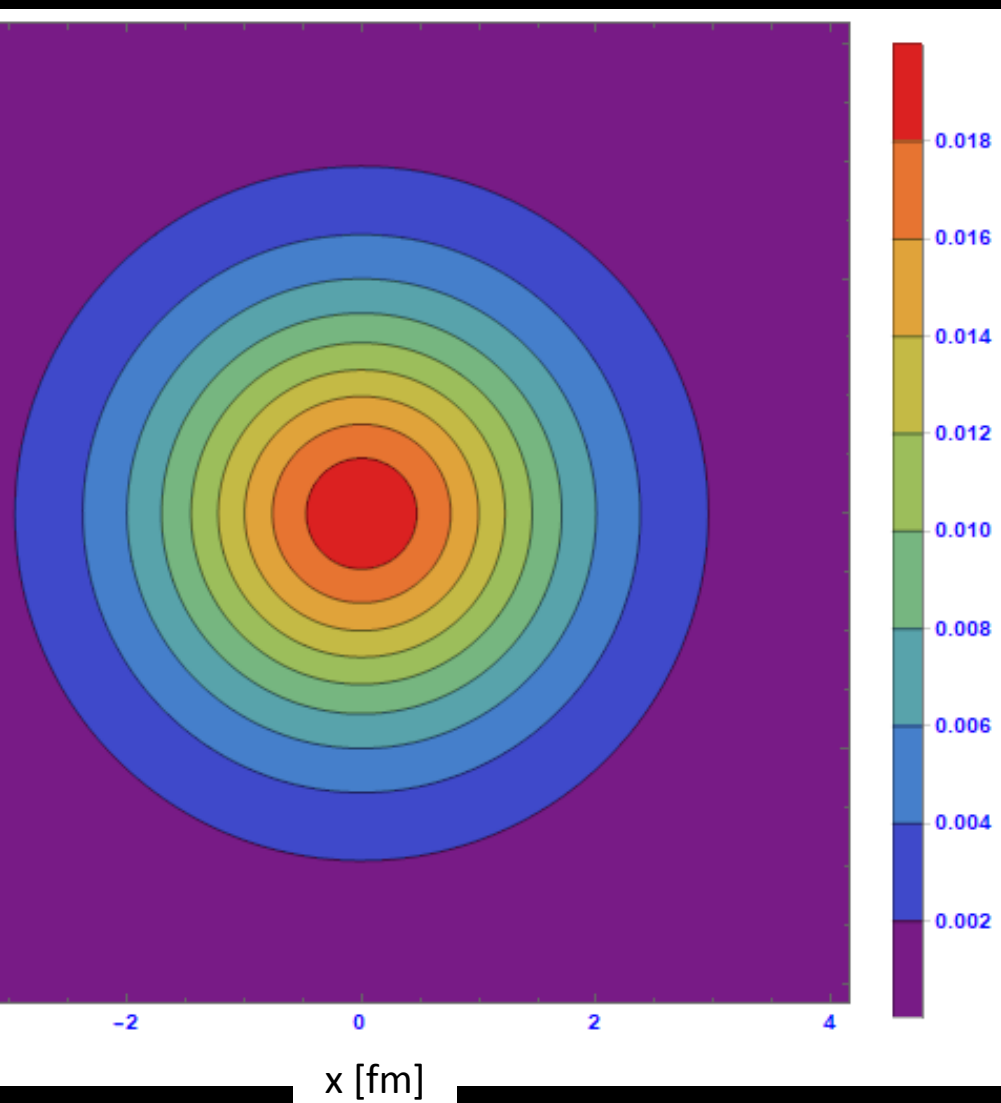

Expansion of r.m.s. Point Charge Radius

r.m.s. radius of the deuterium system during the scattering as a function of

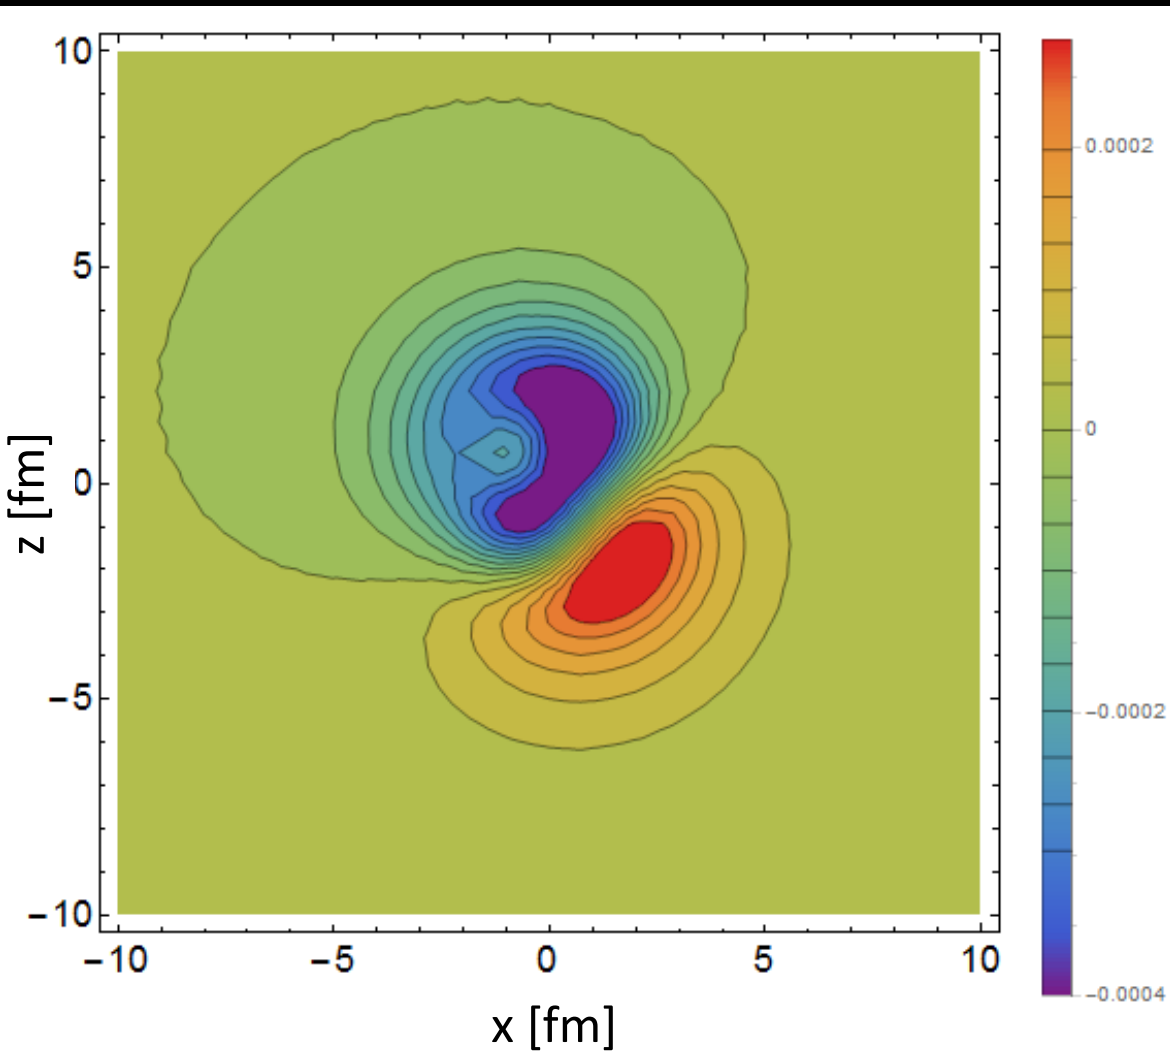

- time
- incident speed

Dynamics: Charge Density Distribution of Initial np system

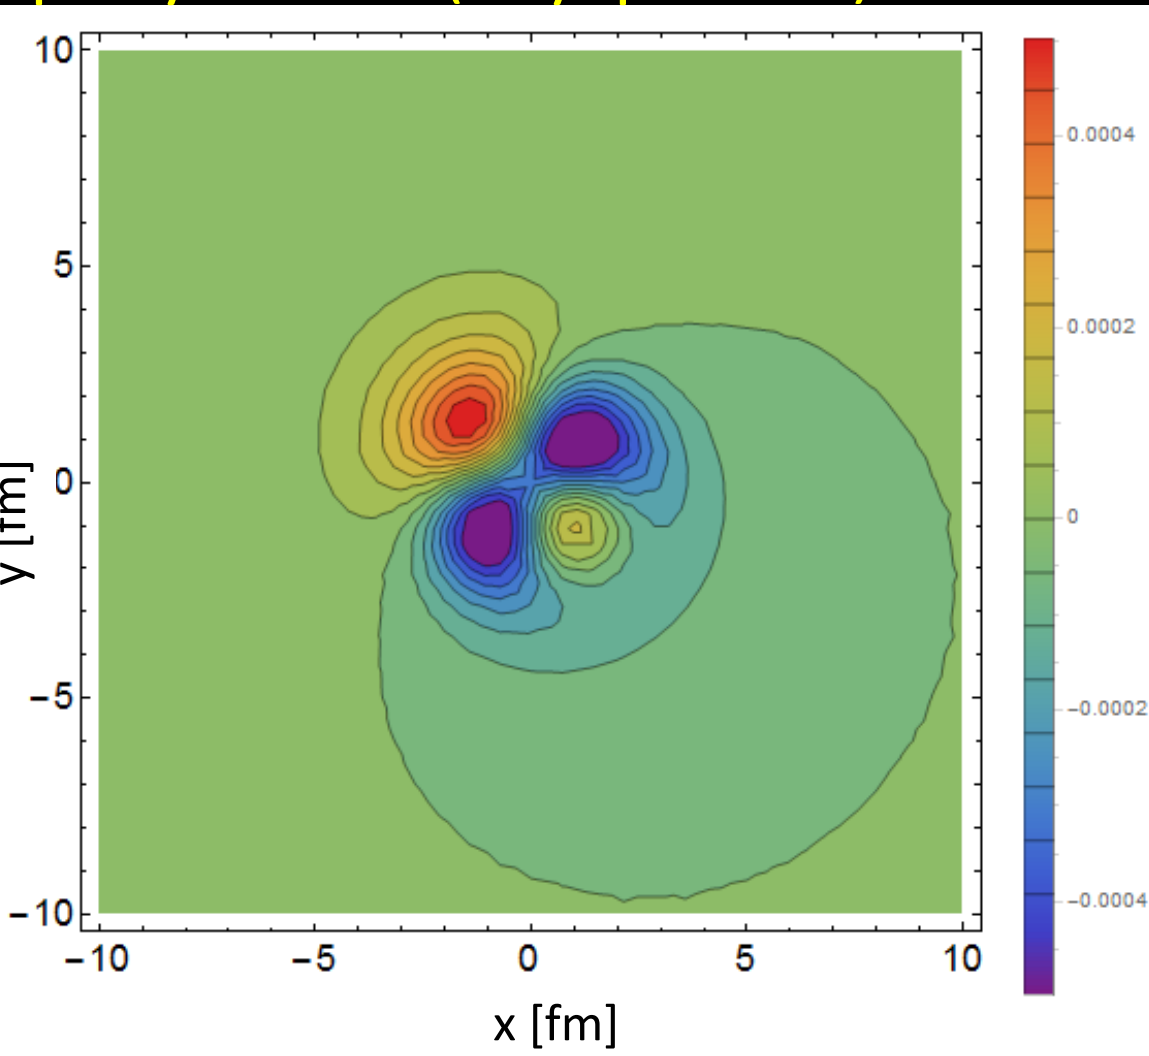

- The Initial polarization is anti-parallel to the z -axis

Change in Charge Density Distribution of Scattered np System (x-z plane) at $T = 0.23 \text{ MeV}^{-1}$

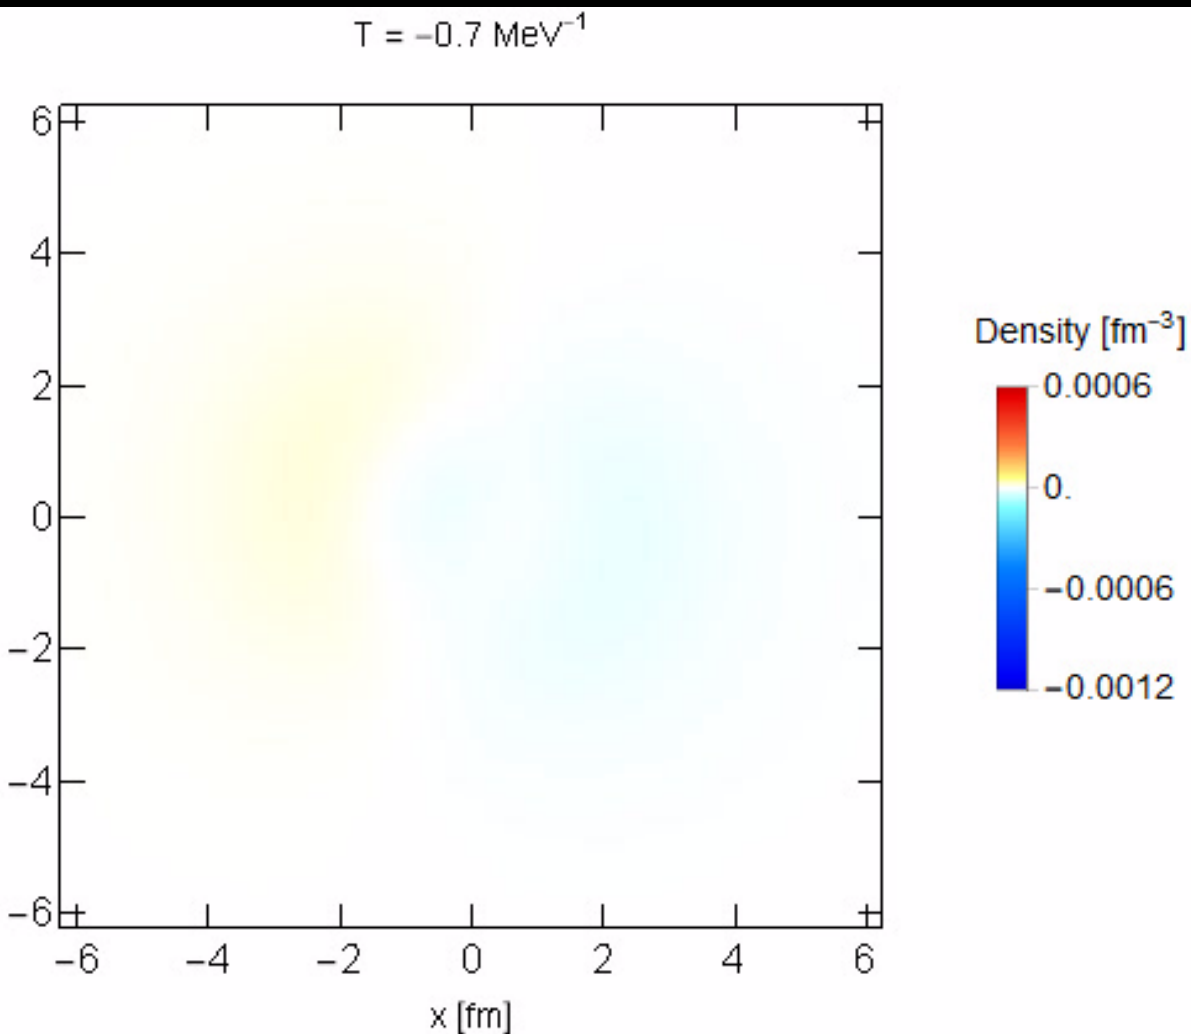

- The difference in charge density distributions between the evolved and the initial np system
- Note the polarization of the charge density distribution

Change in Charge Density Distribution of Scattered np System (x-y plane) at $T = 1.975 \text{ MeV}^{-1}$

- Density fluctuation
- Excitation of orbital angular momentum

Dynamics Revealed by Animation (x-y Plane)

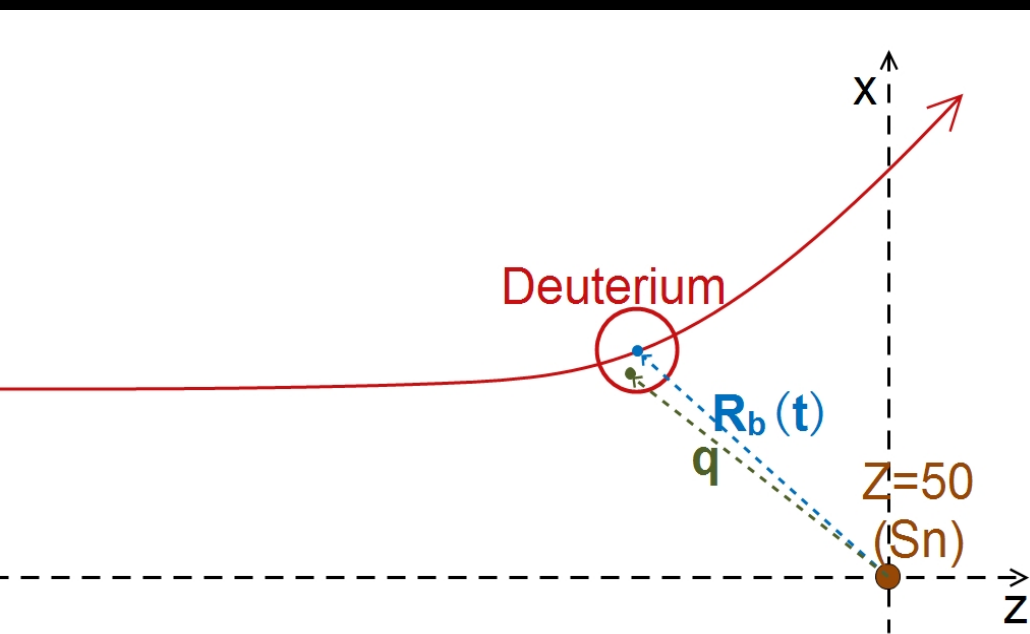

How to interpret?

- The polarization of charge distribution when HI approaches
- The excitation of rotational degree of freedom
- The excitation of oscillational degree of freedom

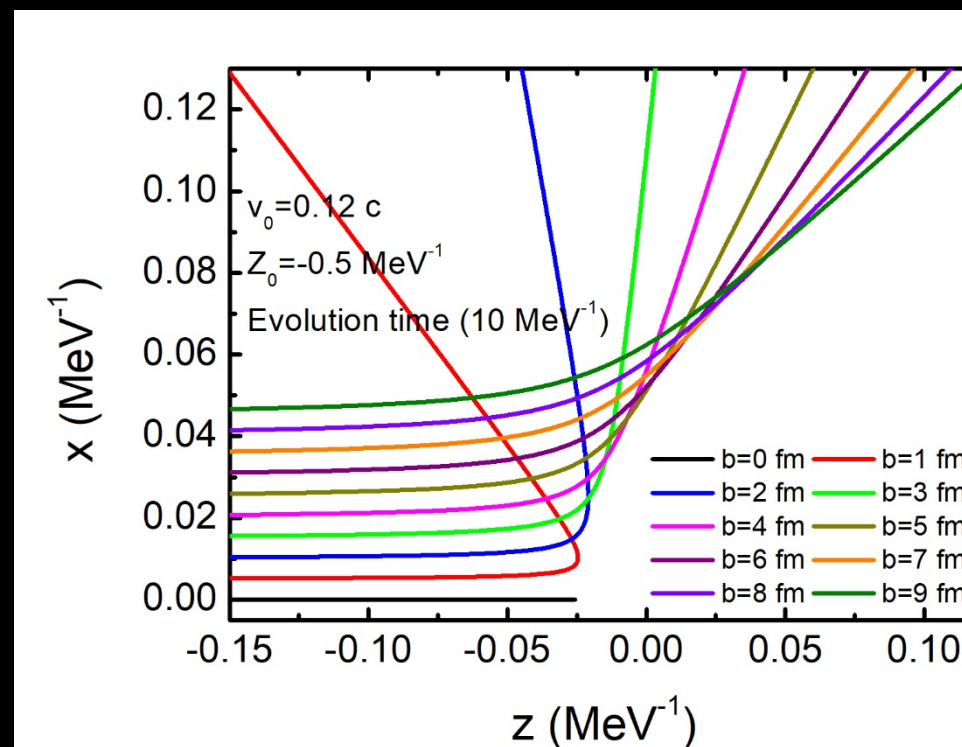

Recent Progress

Population in 51 States After Scattering

- Rutherford Scat
- First Order Perturbation th vs. MSD2

Elastic Cross Section and Average Excitation Energy

Cross section and average excitation energy increases with incident velocity. Both cross section and average excitation energy reach saturation at sufficiently high incident velocity.

Summary

Time-dependent Basis Function (tBF) is motivated by progress both in experimental nuclear physics and in supercomputing techniques

tBF is a **non-perturbative *ab initio*** method for **time-dependent** problems

tBF is particularly suitable for strong, time-dependent, field problems

tBF evaluates at the **amplitude** level - full quantal coherence is retained

tBF is aimed to provide insights into fundamental structure/reaction issues in a detailed and differentiated manner for nuclear reactions

Outlook

Observables: differential cross sections with polarization, inclusive non-linear inelastic response, contributions of 2-body currents, higher-order electromagnetic couplings, . . .

Perform calculation in larger basis space and study convergence with respect to density of states in the continuum

Study the sensitivity with respect to the nuclear Hamiltonian

Include **strong force** in the background field

More realistic center of mass motion

- Trajectory from QMD
- Direct computation of relative motion of the two nuclei (e.g. RGM)

Extend investigations on constraints for the symmetry energy from scattering

Announcement

New faculty position in Nuclear Theory at Iowa State University with support from the DOE Fundamental Interactions Topical Collaboration
