

Near Detector Neutrino Flux with Horn/Current Configurations

14th June 2018 / University of Warwick / DUNE BIWG Meeting

Motivation

Cross-section Calibration

- Accurate reconstruction of true neutrino energy is difficult due to uncertainties from missing p_t techniques and measurements of neutrals.
- Without a well-defined incoming neutrino beam energy, extrapolation to Far Detector without good calibration / well-known ν cross-sections is limited.
- Near Detector cross-section and flux measurements would benefit from some restriction of the wide-band neutrino beam to a more well-defined neutrino energy.

Concept

- Horn currents and configurations can be varied, with the caveat that all powered horns need operate on the same current value.
- We consider 5 options in configuration: A only, A+B, A+C, B+C, and A+B+C
- Tune-ability of neutrino flux over a range of current and configuration settings is shown in the following slides

WARWICK

Linear Combination Fit

- A linear combination of these ND neutrino fluxes can be superposed to fit a number of functions.
- Some refinement of fitting to FD oscillated flux is shown, along with first fits to gaussians

11 Param Thin Gaussian Fits

9 Param Wider Gaussian Fits

12 Param Wider Gaussian Fits

Concluding Remarks

- Current program used for fitting may be somewhat rudimentary compared to full DUNE PRISM analysis. Can aim to echo DUNE PRISM's fitting to improve quality of fit if this becomes a priority
- DUNE PRISM appears to provide a better fit quality (*how much* of this is due to fit program uncertain..), but this avenue may be complementary to DUNE PRISM and provide better coverage of some spectral regions – eg:
 - possible improvement to gaussian fits around 2 GeV,
 - off-axis + horn current could enable better fitting of lower end of spectrum (currently excluded from DUNE PRISM fit below 2nd Osc. Maximum ~0.7GeV),
- More direct coordination with DUNE PRISM / ND plans may provide better focus for further investigation. Currently have a LOT of potential parameters for fitting..
- Modelling response function *could* help find a good/optimal fit analytically

CP Violation at DUNE

The DUNE experiment is the future long-baseline neutrino experiment in the US, and aims to pioneer the advance into high-precision long-baseline neutrino physics measurements with the primary goal of precisely measuring leptonic CP violation. Such measurements require exceptionally low uncertainties, with a necessary signal normalization uncertainty at the level of 2% in order to reach 5 σ sensitivity for 75% of δ_{CP} values with exposures less than ~100k MW \cdot year in the case of the Optimized Design. [1]

Therefore, in order to achieve DUNE's physics goals, systematic uncertainties due to neutrino interaction modelling must be controlled, with 2% taken as a goal for the effect of interaction model uncertainties on the DUNE ν_{μ} signal normalization. This predicted level of interaction uncertainty depends upon the cancellation of near-far uncertainties from isolation of neutrino-nucleon interactions in the Near Detector (ND).

CP Violation sensitivity?

Include plot(s) of CP violation sensitivity?

ν_{μ} Flux with Horn Configurations

Figures show ND muon neutrino flux for several magnetic horn configurations. Under the current design proposal, horns must be run in series when connected, restricting tunability of horn current to one value for all powered horns.

Further Study

Quote some of your summary from presentation for this section.

DUNE PRISM appears to provide a better quality fit, but this avenue may be complementary to DUNE PRISM and provide better coverage of some spectral regions.

Interaction Uncertainties

To make precision neutrino oscillation measurements, the energy of each interacting neutrino must be precisely determined. This is difficult due to our understanding of the outgoing leptonic and hadronic final states of neutrino-nucleus interactions, particularly the fraction of “missing” energy due to unseen neutrons and low energy hadrons.

Whilst a projected improved model of neutrino interactions from the program of more immediate experiments like ProtoDUNE will reduce the impact of imperfect reconstruction of energy on the DUNE analysis, an experimental solution to the neutrino energy measurement problem can be provided by producing a set of measurements of neutrino-nucleus interactions at the ND, with a range of different incident neutrino energy spectra. This would allow for the association of incident neutrino energy to the distribution of experimental observables without heavy reliance on modelling of neutrino-nucleus interactions.

This idea is the basis of the current DUNE PRISM program, which relies on movement of the ND to a number of off-axis positions to form this set of measurements. A similar measurement set could be produced by tuning with a variety of powered magnetic horn configurations, using different combinations of the three horns, labelled A, B and C, over some set of currents.

Linear Flux Combinations

Analogous to the DUNE PRISM analysis, one avenue to reduce these uncertainties is through the linear combination of various near detector fluxes to construct the expected oscillated energy spectrum at the far detector for a chosen set of oscillation parameters, allowing a direct comparison of near and far detector flux such that like-uncertainties between detectors, for instance those from missing energy, will cancel. This can result in a significant de-coupling of the flux and neutrino interaction uncertainties.

In this way, resulting linearly combined measurements can be used to effectively calibrate the relationship between observed and true neutrino energies. A first analysis of the utility of this technique with this set of spectra is shown.

Far Detector Oscillated ν_{μ} Flux Fitting

These fits have been performed using a first fit analysis showing reasonable agreement over a number of fitted spectra, with the goal of improving upon these results with a fewer number of horn configurations required so as to minimise time running non-optimal beamline configurations for the far detector.
