

Using Sparse Convolutional Neural Networks in MicroBooNE

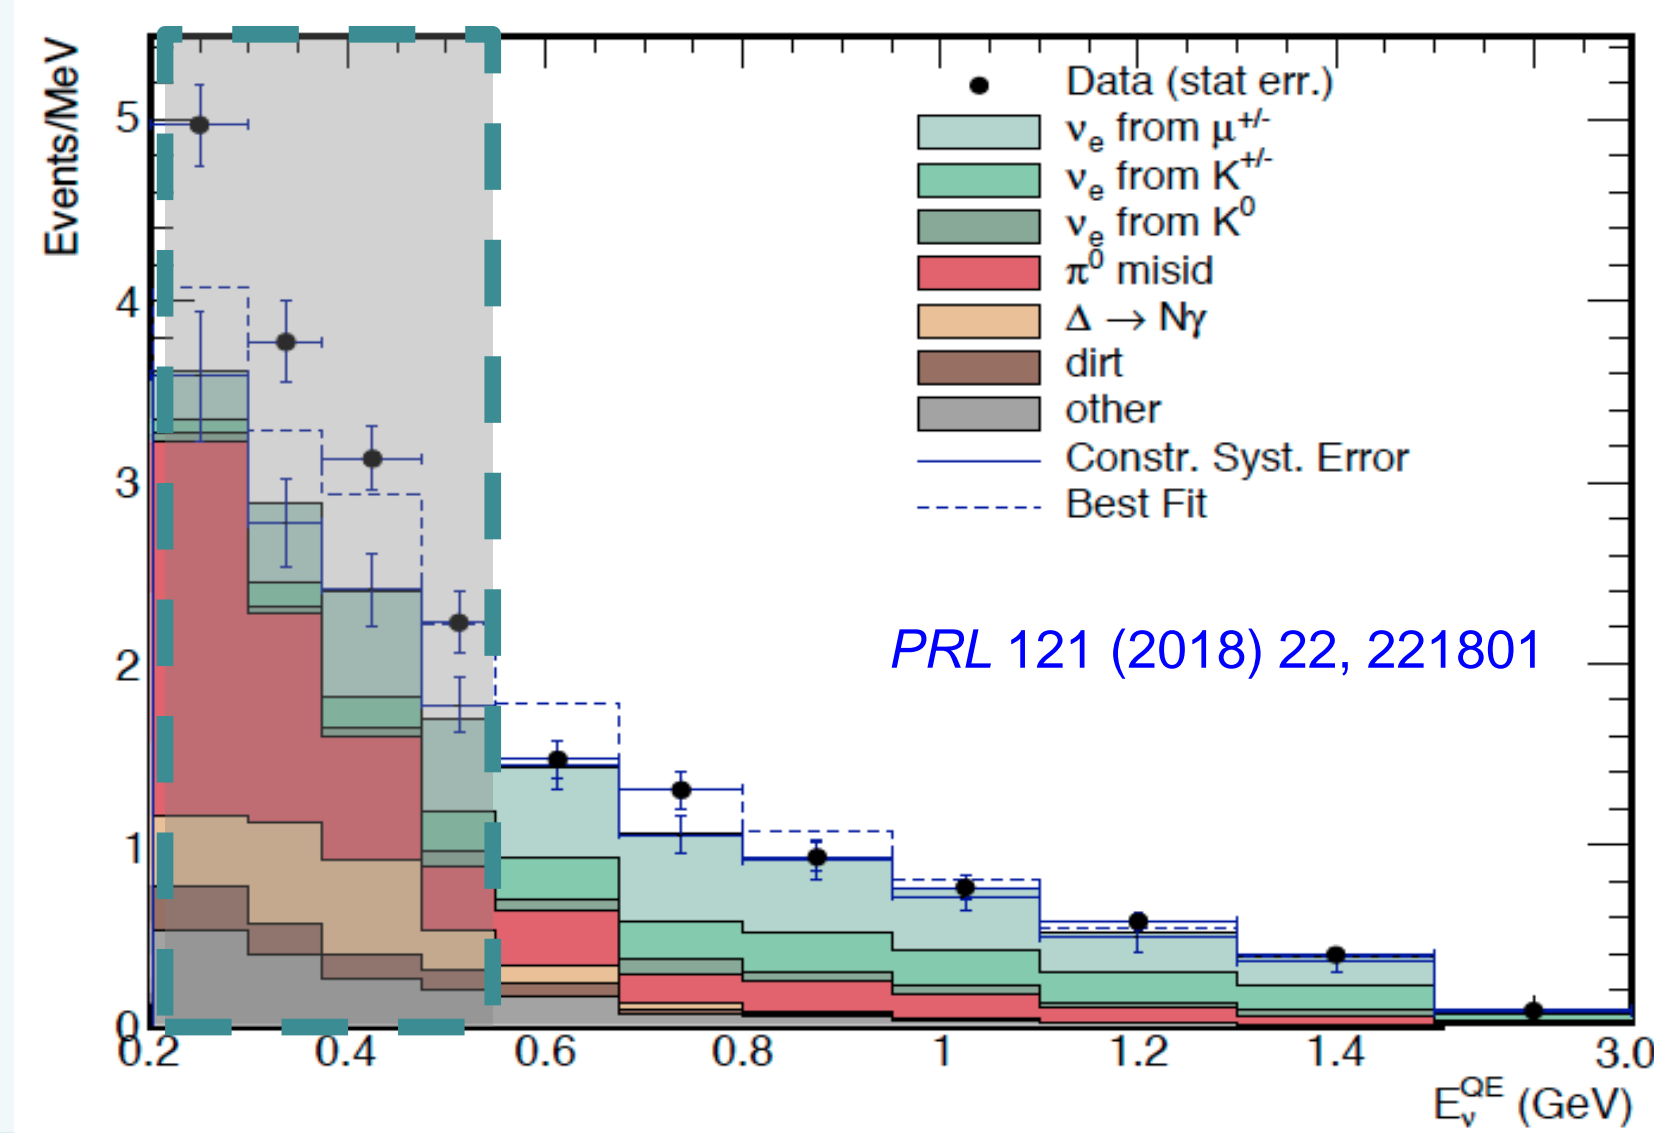

Ran Itay, representing the MicroBooNE collaboration
ranitay@stanford.edu

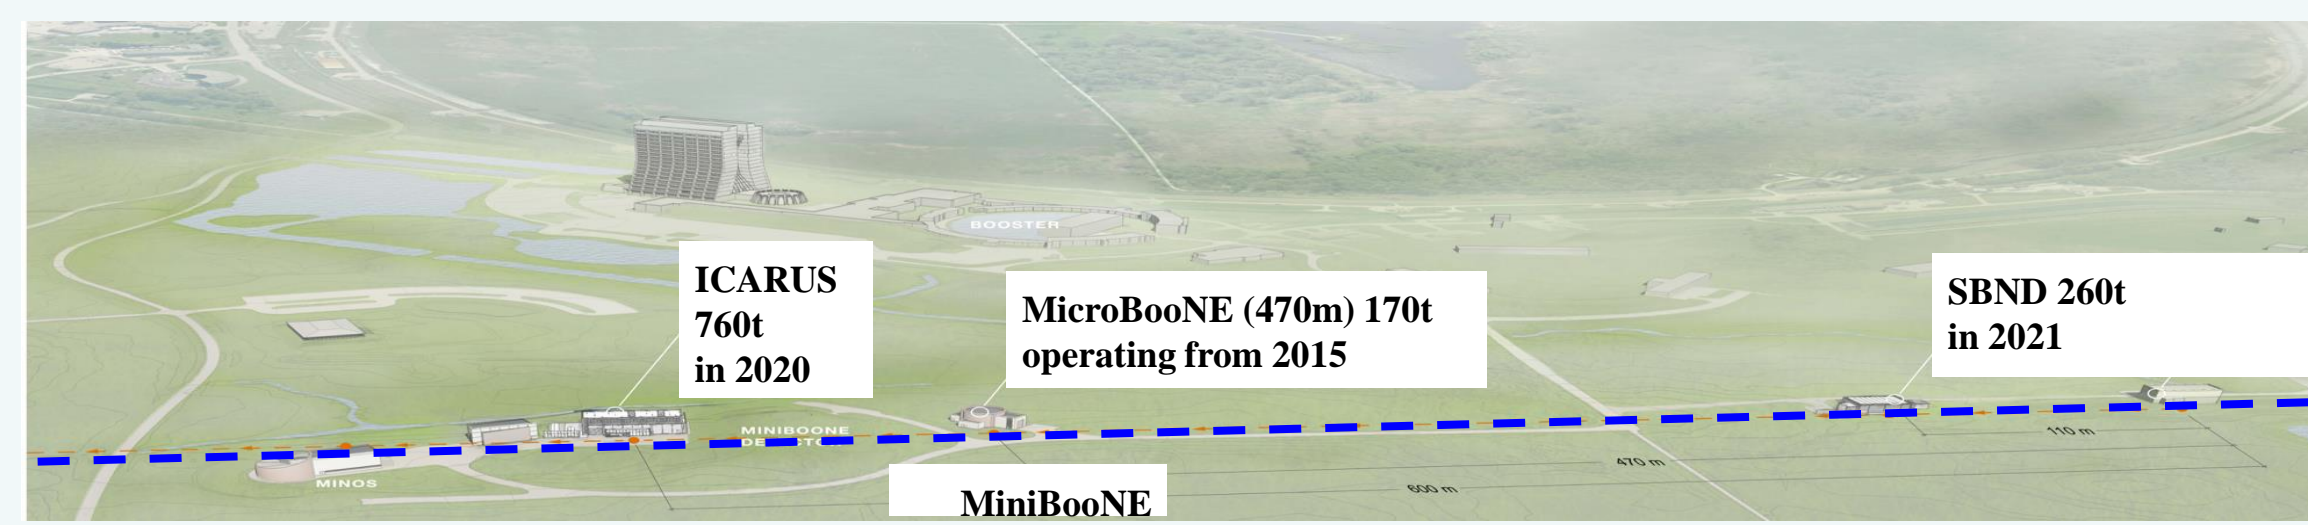

Motivation

- MiniBooNE sees 4.5σ ν_e -like
- Low Energy Excess (LEE)
- Compatible with 3+1 model.
- Tension with other experiment
- Limited capability to distinguish e vs γ

The MicroBooNE Detector

- MicroBooNE
 - Same beam (BNB)
 - Similar baseline
 - LArTPC (85 tons of LAr active mass)
 - 3 planes of sense wires
- Goals
 - LEE search
 - Cross-section measurements
 - Detector physics (DUNE)

- Dominated by CCQE 1L1P events
 - $1e1p$ – signal
 - $1\mu1p$ – constraining flux, systematics
- Shower Vs Track - Distinct topologies
- Semantic segmentation (PRD 99 (2019) 9, 092001)
- γ, π^0 Vs e - Gap from vertex

SparseSSNet

- Sparse Submanifold Convolutional Network (CVPR.2018.00961)
- Prior training define mask (e.g., >0 pixels)
- Remove all masked pixels ($\sim 99.5\%$)
 - Reduce memory consumption ($\sim 1\text{GB}$ / image)
 - Reduce inference time (~ 0.5 sec / image)
 - Prevent dilation of sparse image
- Distinct model for each plane

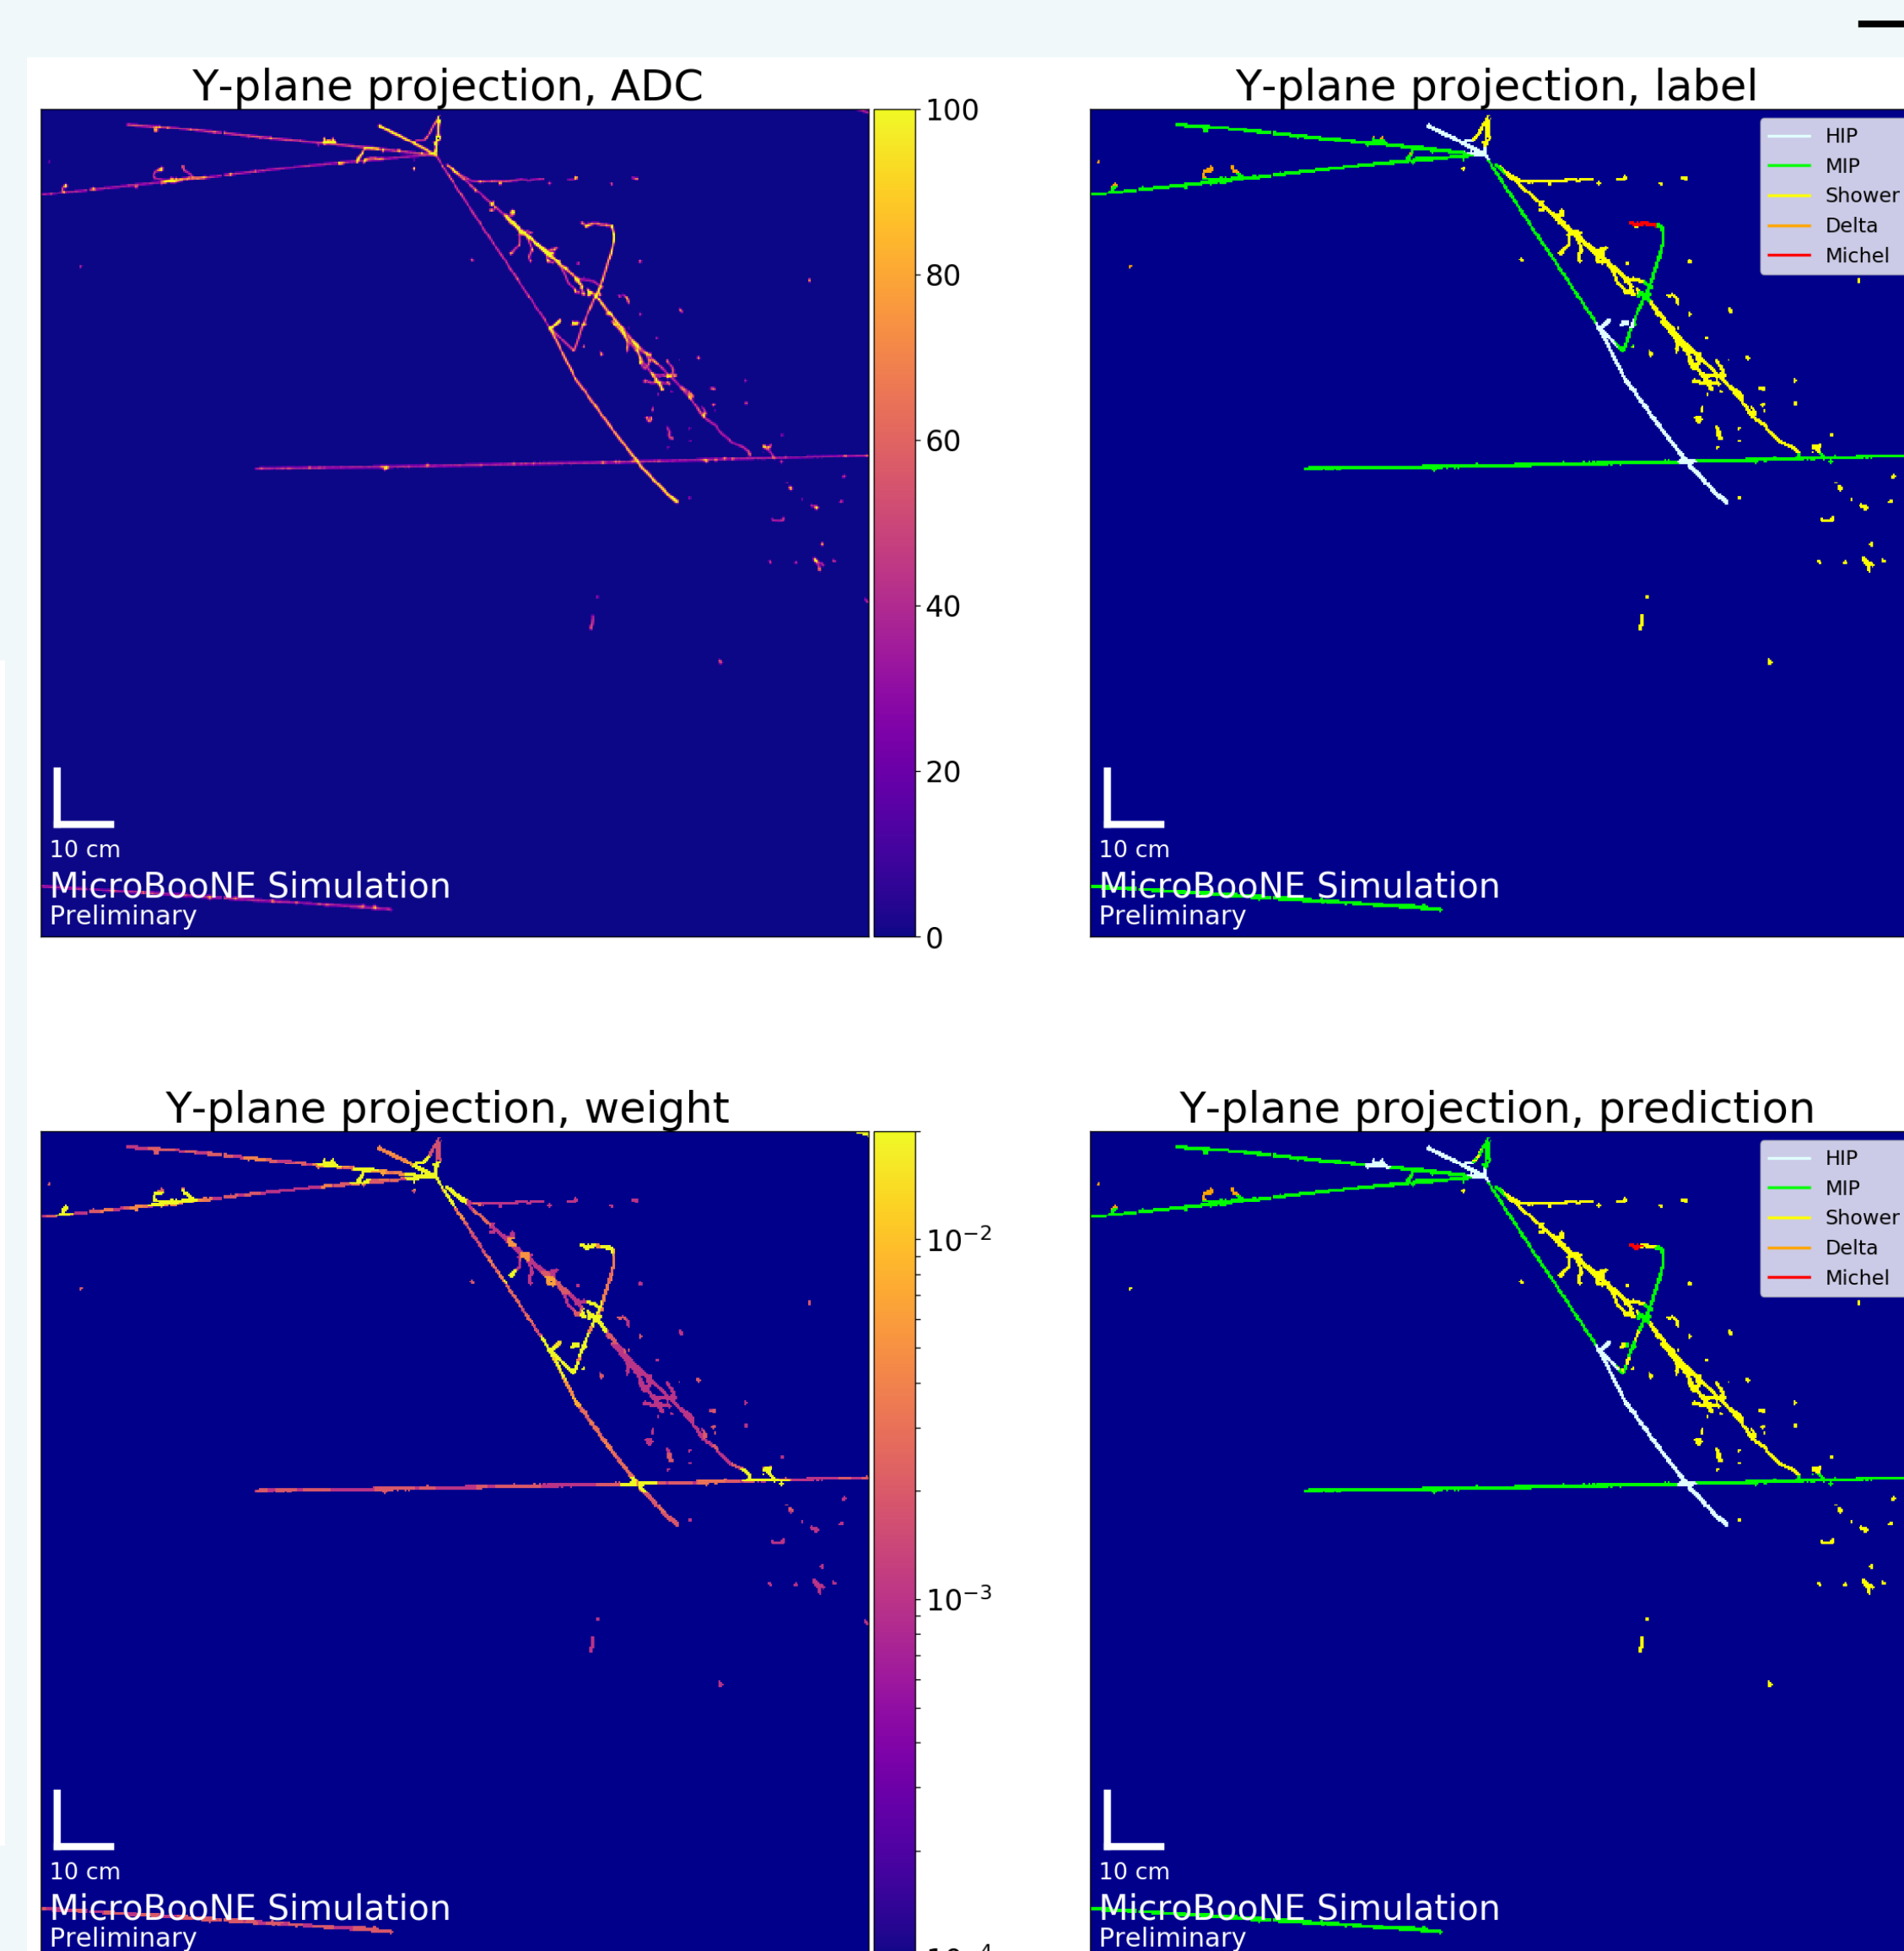

Results:

- Pixel-weight to prevent class imbalance
- Single hot labels: HIP, MIP, shower, delta, Michel

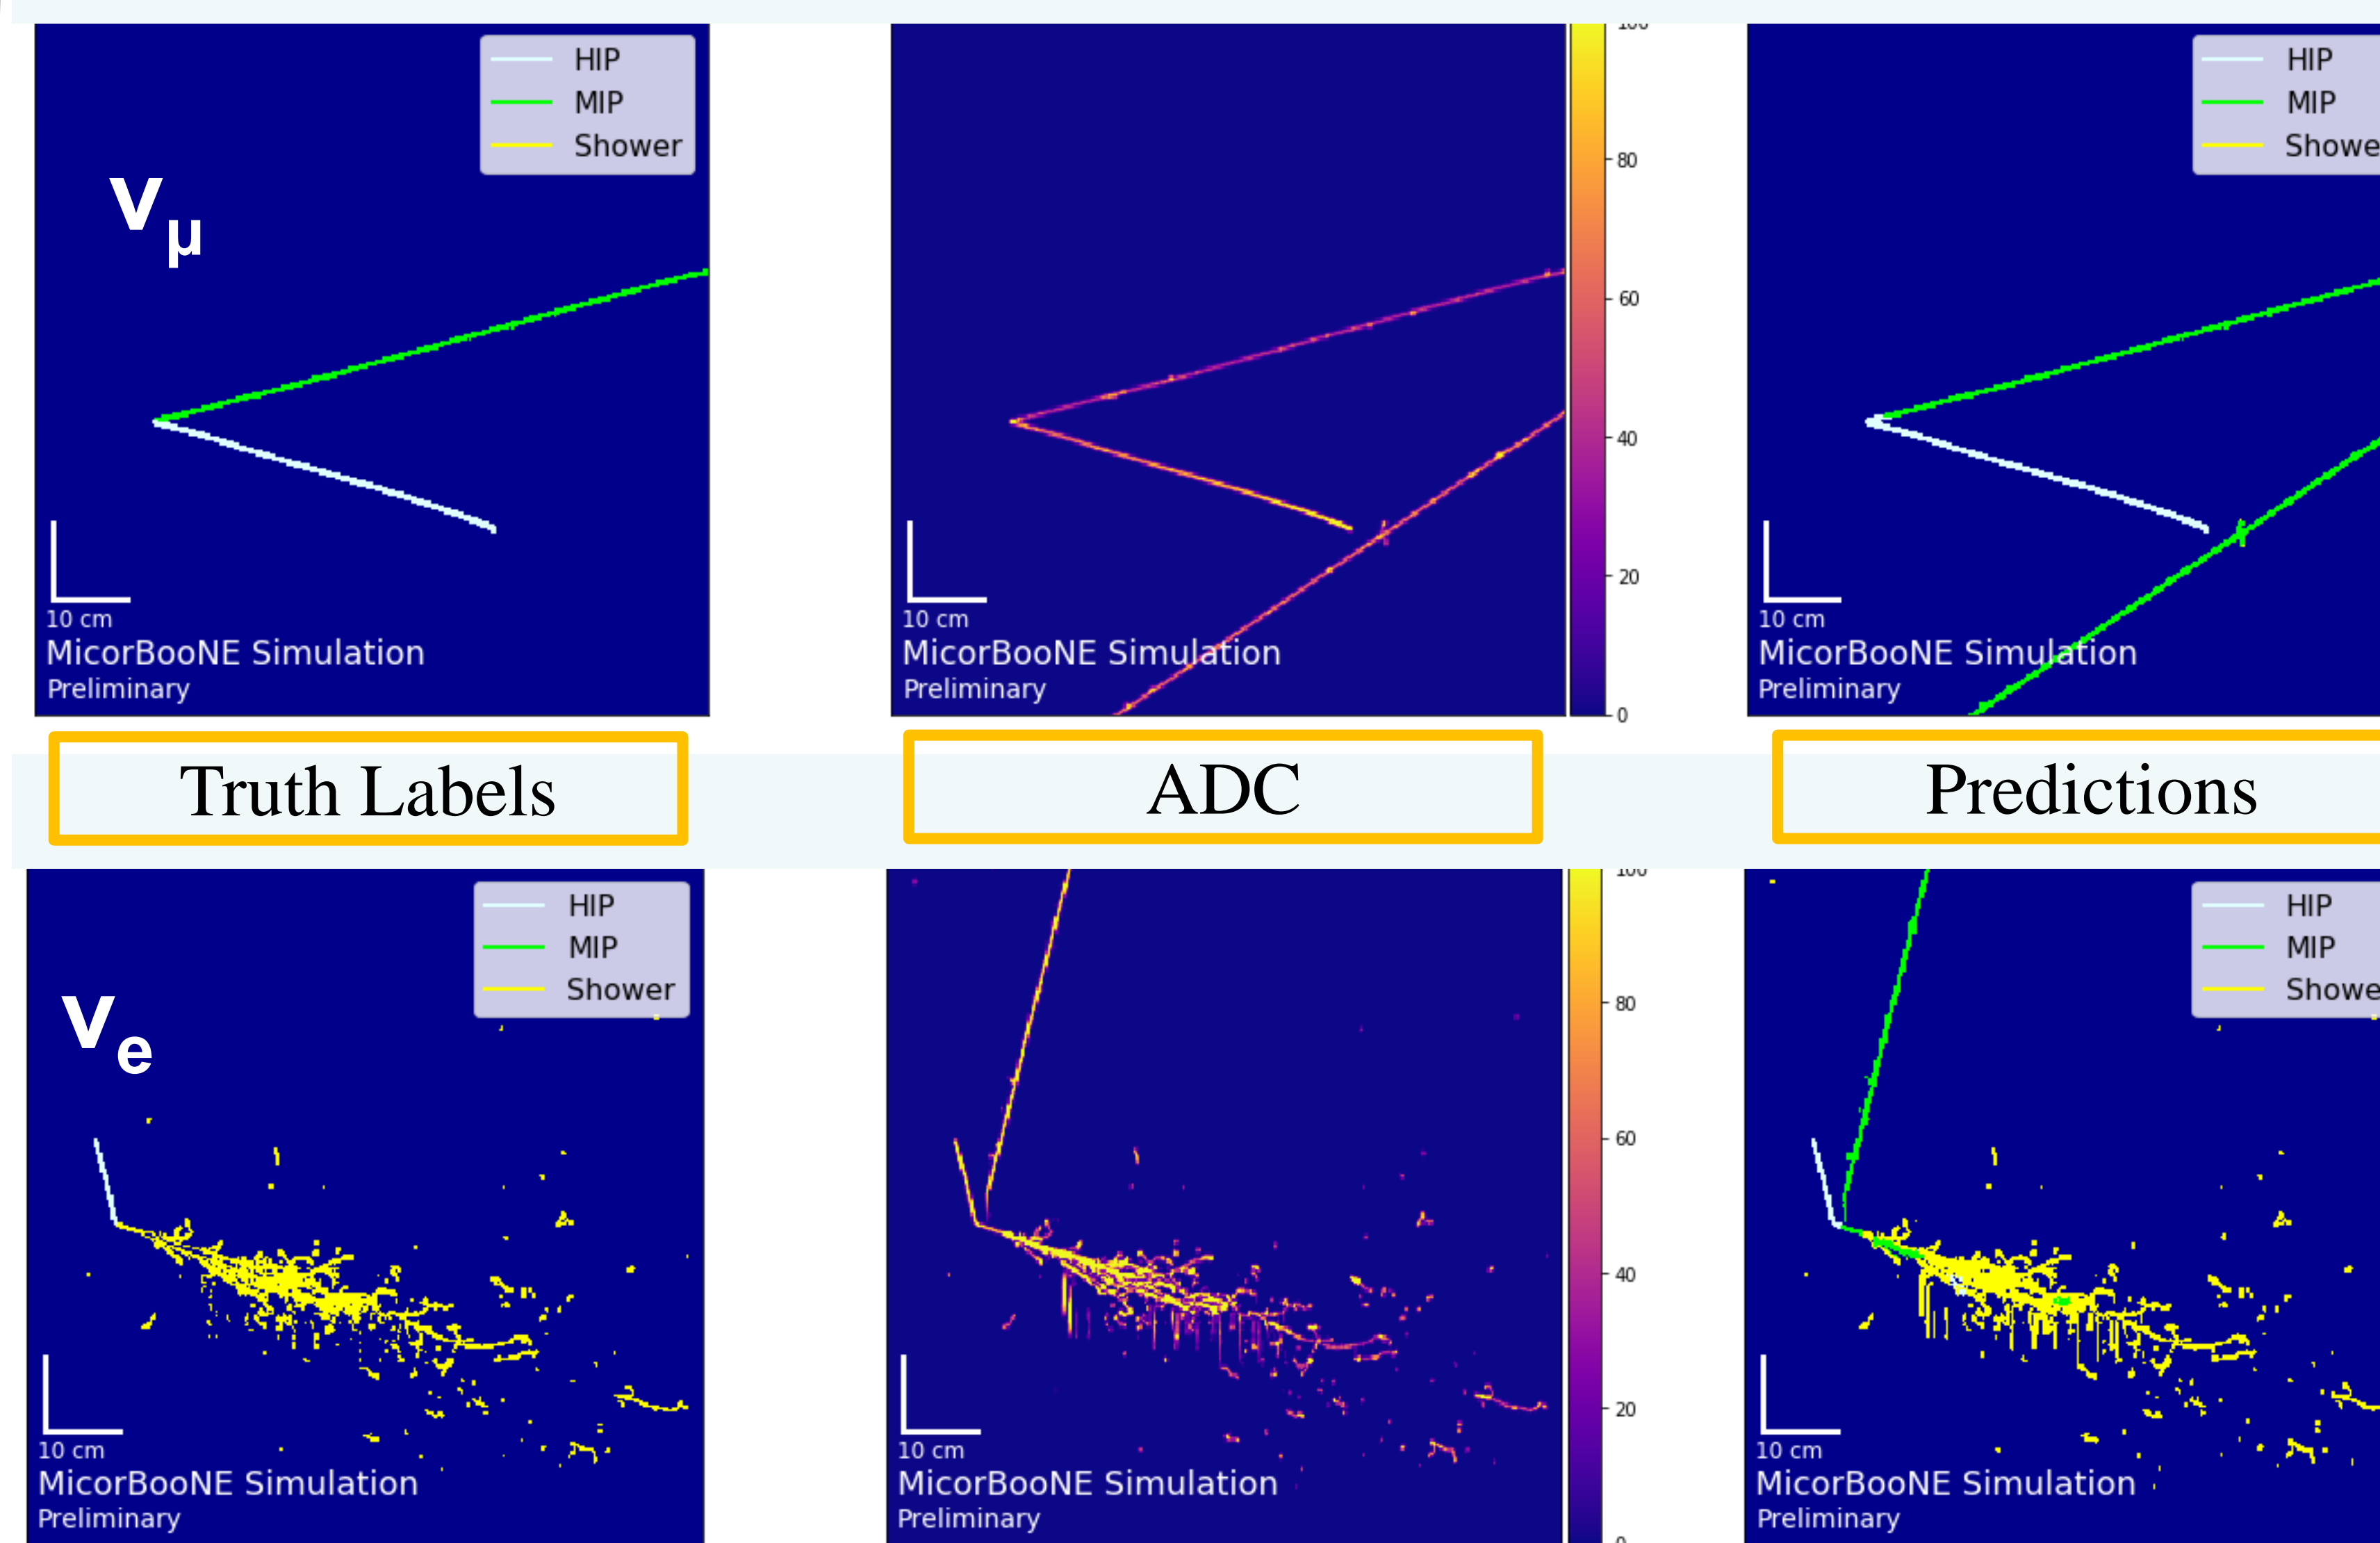

Y - Plane
MicroBooNE, Preliminary

	HIP	MIP	Shower	Delta	Michel
HIP	0.928	0.009	0.003	0.000	0.001
MIP	0.066	0.981	0.021	0.028	0.021
Shower	0.006	0.009	0.941	0.188	0.100
Delta	0.000	0.002	0.033	0.782	0.035
Michel	0.000	0.000	0.003	0.002	0.843

Test sample

ν interaction sample

Summary

SparseSSNet Improvements:

Entire image instead of 64 crops.

Memory usage $\sim \text{GB}/\text{full_image}$

Time $\sim 0.5\text{s}/\text{full_image}$ (CPU)

Higher accuracy ($\sim 99\%$), No "dilation" of data
