Presented on behalf of the Semi-Visible Jets Analysis Team:

- University of Rochester
  - Colin Fallon
  - Aran Garcia-Bellido
  - C.L. Keane Tan
- Universitaet Zuerich
  - Annapaola De Cosa
  - Giorgia Rauco
- University of Bristol
  - Eshwen Bhal
  - Henning Flacher
  - Benjamin Krikler

- Fermi National Accelerator Laboratory
  - Kevin Pedro
  - V. Daniel Elvira
  - Steven Mrenna
- University of Maryland

Sarah Eno

#### 1 Introduction

#### 2 Dark Matter and Hidden Valley

- Hidden Valley Theory
- Semi-Visible Jets

#### 3 The Analysis

A BDT for Jet Tagging

< □ > < □ > < □ > < Ξ > < Ξ > Ξ の Q · 3/17

The Bump Hunt

#### Searching

- This analysis is a Work-In-Progress.
- These plots are not official.
- Please do not distribute these slides outside this conference.

This presentation will deal mostly with the theory that allows for Semi Visible Jet production at hadron colliders anyway, but towards the end there are some MC plots that are technically WIP.

4 ロ ト 4 母 ト 4 王 ト 4 王 ト 王 - の Q C - 4/17

#### What is Dark Matter?

- Practically Anything that isn't Standard Model matter
- Experimentally Astronomical observations
- Theoretically Pick your poison!
  - SuperSymmetry!
  - It Doesn't Exist! (Entropic Gravity, and others...)

Hidden Valley

#### 2 Minute Primer on Hidden Valley Dark Matter

- The realm of Dark Matter is a second gauge group  $(G_v)$  that exists independently of the SM gauge group  $(G_{SM})$ .
- All SM particles are neutral in the  $G_v$  gauge, while all HV particles are neutral in the  $G_{SM}$  gauge.

#### Connecting SM to HV

If the two gauge groups are independent, how can SM colliders produce DM?

- To 'bridge the gap' between SM and HV, a messenger particle is postulated that is charged under both gauges.
- This messenger, hereafter referred to as Z', can be produced by and can decay into both SM and HV particles.

#### What could the HV sector look like?

- If G<sub>v</sub> is made up of a QCD-like gauge, then dark matter would be comprised of dark quarks which form dark hadrons.
- Here we have a realativly simple sector of two dark quarks and dark gluons to bind them.

#### Side Note: Whats a Jet!?

Jet:

- a cone of hadrons produced from the hadonization of quarks and gluons
- Jets exist because of color confinement of QCD.
- Jets are not *detected* but reconstructed through jet clustering algorithms.

 This is a Jet (yellow) that has many particles (red) and is 'inline' with the Missing Transverse Energy (green)

#### How does that HV sector produce Semi-Visible Jets?

- SM quarks interact and produce a Z'.
- The messenger does as its name implies and decays into a pair of dark quarks.
- These initial dark quarks hadronize, and form two dark mesons.
- Heavy dark matter mesons would decay through 'dark' hadronization; light dark mesons are stable.

#### How does that HV sector produce Semi-Visible Jets?

- Dark hadronization will produce more Z' messengers and light dark mesons.
- These Z' messengers can then decay into more HV mesons or back into SM hadrons.
- SM hadrons will hadronize.
- This continues until all that remains are light dark mesons and SM hadrons.

# Thats how SemiVisible Jets are produced, but how can we find them?

< □ ▶ < @ ▶ < ≧ ▶ < ≧ ▶ E のへで 12/17

Event Display Plot of Signal MC at GEN level

 Standard cut-based analysis to select events and filter backgrounds, but that's not good enough...

Reality is much more grim, with low  $\Delta \phi$  events being popular in all our backgrounds

#### Tag them with a Boosted Decision Tree

Girth,  $\tau_{21}$ ,  $\tau_{32}$ , SoftDrop Mass, min $\Delta \phi$ , Major and Minor Axis, ptD, energy correlation functions, ptdrlog, particle type energy fractions, *b*-tagging variable

- Form of Machine Learning
- Finds a set of 1D cuts to identify signal and background
- In this case, we're using the BDT to tag individual jets as a SVJ or not.

< □ > < @ > < E > < E > E の < C 14/17

Used often for resonant searches. Typically use an invariant mass, where it be dijet mass, jet-lepton mass, diphoton mass...

However, the dijet mass of SVJs doesn't really look too nice for a bump hunt...

#### Hunt for a better Bump!

### Instead, we use the transverse mass variable:

$$m_{T} = \sqrt{m_{jj}^{2} + 2(\sqrt{m_{jj}^{2} + p_{Tjj}^{2}}\mathcal{E}_{T} - \vec{p}_{Tjj} \cdot \vec{\mathcal{E}_{T}})}$$

#### CMS Simulation (work-in-progress)
