# BSM Physics from Kaon Decays 

# Lattice QCD at Fermilab: <br> Celebrating the Career of <br> Paul Mackenzie 

November 7-8, 2019
N.H. Christ

RBC/UKQCD Collaboration

## Outline

- Thoughts about Paul
- Physics
$-K_{L} \rightarrow \mu^{+} \mu^{-}$
- $K \rightarrow \pi \pi$ decay and $\varepsilon^{\prime}$
- Conclusions

## Thoughts about Paul

- Many places where Paul's work has had a large impact on me:
- Tadpole improvement of lattice perturbation theory.
- QCD machines: ACPMAPS
- Fermilab heavy quark action
- Founding member and then spokesperson for USQCD.

- Common physics goal of searching for phenomena not predicted by the standard model.

## $K \rightarrow \mu^{+} \mu^{-}$

## Physics of $K_{L} \rightarrow \mu^{+} \mu^{-}$

- A second order weak, ``strangeness changing neutral current"

(Cirigliano, et al. , Rev. Mod. Phys., 84, 2012)
- $K_{L} \rightarrow \mu^{+} \mu^{-}$decay rate is known:
$-\operatorname{BR}\left(K_{L} \rightarrow \mu^{+} \mu^{-}\right)=(6.84 \pm 0.11) \times 10^{-9}$
- Large "background" from two-photon process:
- Third-order electroweak amplitude
- Optical theorem gives imaginary part.
- $K_{L} \rightarrow \gamma \gamma$ decay rate is known

## Physics of $K_{L} \rightarrow \mu^{+} \mu^{-}$(con't)

- Define: $\frac{\Gamma\left(K_{L} \rightarrow \mu^{+} \mu^{-}\right)}{\Gamma\left(K_{L} \rightarrow \gamma \gamma\right)}=2 \beta_{\mu}\left(\frac{\alpha}{\pi} \frac{m_{\mu}}{M_{K}}\right)^{2}\left(\left|F_{\text {imag }}\right|^{2}+\left|F_{\text {real }}\right|^{2}\right)$
- Optical theorem + experiment determine:

$$
\left|F_{\text {real }}\right|=\left|\left(F_{\text {real }}\right)_{E \& M}+\left(F_{\text {real }}\right)_{\text {Weak }}\right|=1.167 \pm 0.094
$$

- Standard model: $\left(F_{\text {real }}\right)_{\text {Weak }}=-1.82 \pm 0.04$
- A $10 \%$ lattice calculation of $\left(F_{\text {real }}\right)_{E \& M}$ would allow a test of $\left(F_{\text {real }}\right)_{\text {Weak }}$ with $6-17 \%$ accuracy
- Lattice calculation more difficult than $\Delta M_{K}$
- 5 vertices, 60 time orders
- many states $\mid \mathrm{n}>$ with $E_{\mathrm{n}}<M_{K}$
- First try simpler $\pi^{0} \rightarrow e^{+} e^{-}$

## Consider simpler $\pi^{0} \rightarrow e^{+} e^{-}$

- Euclidean non-covariant P.T. difficult:
- 12 time orders,
- $E_{\gamma \gamma}<M_{\pi 0}$
- Try something different:
- Evaluate in Minkowski space
- Wick rotate internal time integral:
$\mathcal{A}_{\pi^{0} \rightarrow e^{+} e^{-}} \rightarrow \int d^{4} W \widetilde{L}\left(k_{-}, k_{+}, W\right){ }_{\mu \nu}\langle 0| T\left\{J_{\mu}\left(\frac{W}{2}\right) J_{\nu}\left(-\frac{W}{2}\right)\right\}\left|\pi^{0}(\vec{P}=0)\right\rangle$

## Lattice Results

(Yidi Zhao)

$$
\mathcal{A}_{\pi^{0} \rightarrow e^{+} e^{-}} \rightarrow \int d^{4} w \widetilde{L}\left(k_{-}, k_{+}, w\right)_{\mu \nu}\langle 0| T\left\{J_{\mu}\left(\frac{W}{2}\right) J_{\nu}\left(-\frac{W}{2}\right)\right\}\left|\pi^{0}(\vec{P}=0)\right\rangle
$$

- Lattice result is literally complex:
- Exponentially small FV corrections
- Physical kinematics, $1 / a \leq 1.73 \mathrm{GeV}$ :
- $\operatorname{Im}(A)=35.94(1.01)(1.09) \quad[E x p t: 35.07(37)]$
- $\operatorname{Re}(A)=20.39(72)(70) . \quad$ [Expt: 21.51(2.02)]

## $K \rightarrow \pi \pi$ decay and $\varepsilon^{\prime}$

## Cabibbo-Kobayashi-Maskawa mixing

- $W^{ \pm}$emission scrambles the quark flavors

$$
\begin{gathered}
\left(\begin{array}{c}
u \\
c \\
t
\end{array}\right) \stackrel{W}{\longleftrightarrow}\left(\begin{array}{ccc}
V_{u d} & V_{u s} & V_{u b} \\
V_{c d} & V_{c s} & V_{c b} \\
V_{t d} & V_{t s} & V_{t b}
\end{array}\right)\left(\begin{array}{c}
d \\
s \\
b
\end{array}\right) \\
\left(\begin{array}{ccc}
V_{u d} & V_{u s} & V_{u b} \\
V_{c d} & V_{c s} & V_{c b} \\
V_{t d} & V_{t s} & V_{t b}
\end{array}\right)=\left(\begin{array}{ccc}
1-\frac{\lambda^{2}}{2} & \lambda & A \lambda^{3}(\bar{\rho}-i \bar{\eta}) \\
-\lambda & 1-\frac{\lambda^{2}}{2} & A \lambda^{2} \\
A \lambda^{3}(1-\bar{\rho}-i \bar{\eta}) & -A \lambda^{2} & 1
\end{array}\right)+\mathcal{O}\left(\lambda^{4}\right) \\
\lambda=0.22535 \pm 0.00065, \\
\bar{\rho}=0.131_{-0.013}^{+0.026},
\end{gathered} \quad \begin{gathered}
\text { CP } \\
\lambda=0.811_{-0.012}^{+0.022}
\end{gathered}
$$

## CP violation

- CP violating, experimental amplitudes:

$$
\begin{aligned}
\eta_{+-} & \equiv \frac{\left\langle\pi^{+} \pi^{-}\right| H_{w}\left|K_{L}\right\rangle}{\left\langle\pi^{+} \pi^{-}\right| H_{w}\left|K_{S}\right\rangle}=\epsilon+\epsilon^{\prime} \\
\eta_{00} & \equiv \frac{\left\langle\pi^{0} \pi^{0}\right| H_{w}\left|K_{L}\right\rangle}{\left\langle\pi^{0} \pi^{0}\right| H_{w}\left|K_{S}\right\rangle}=\epsilon-2 \epsilon^{\prime}
\end{aligned}
$$

- Where:

Indirect: $|\varepsilon|=(2.228 \pm 0.011) \times 10^{-3}$
Direct: $\operatorname{Re}\left(\varepsilon^{\prime} / \varepsilon\right)=(1.66 \pm 0.23) \times 10^{-3}$

## Direct CP violation in $K \rightarrow \pi \pi$

- Final $\pi \pi$ states can have $/=0$ or 2 .

$$
\begin{aligned}
\langle\pi \pi(I=2)| H_{w}\left|K^{0}\right\rangle & =A_{2} e^{i \delta_{2}} & \Delta I=3 / 2 \\
\langle\pi \pi(I=0)| H_{w}\left|K^{0}\right\rangle & =A_{0} e^{i \delta_{0}} & \Delta I=1 / 2
\end{aligned}
$$

- CP symmetry requires $A_{0}$ and $A_{2}$ be real.
- Direct CP violation in this decay is characterized by:

$$
\epsilon^{\prime}=\frac{i e^{\delta_{2}-\delta_{0}}}{\sqrt{2}}\left|\frac{A_{2}}{A_{0}}\right|\left(\frac{\operatorname{Im} \boldsymbol{A}_{2}}{\operatorname{Re} \boldsymbol{A}_{2}}-\frac{\operatorname{Im} \boldsymbol{A}_{0}}{\operatorname{Re} \boldsymbol{A}_{0}}\right) \quad \begin{array}{|c|}
\begin{array}{c}
\text { Direct CP } \\
\text { violation }
\end{array} \\
\hline
\end{array}
$$

## Low Energy Effective Theory

- Represent weak interactions by local four-quark Lagrangian $\mathcal{H}^{\Delta S=1}=\frac{G_{F}}{\sqrt{2}} V_{u d} V_{u s}^{*}\left\{\sum_{i=1}^{10}\left[z_{i}(\mu)+\tau y_{i}(\mu)\right] Q_{i}\right\}$
- $\tau=-\frac{V_{t d} V_{t s}^{*}}{V_{u d} V_{u s}^{*}}=(1.543+0.635 i) \times 10^{-3}$
- $V_{q q^{\prime}}$ CKM matrix elements
- $z_{i}$ and $y_{i}$-Wilson Coefficients
- $Q_{i}$ - four-quark operators

## Lattice calculation of $\langle\pi \pi| H_{W}|K\rangle$

- The operator product $\bar{d}(x) s(x)$ easily creates a kaon.
- Use finite-volume energy quantization (Lellouch-Luscher) and adjust $L$ so that $n^{\text {th }}$ excited state obeys: $E_{\pi \pi}^{(n)}=M_{K}$

$p=2 \pi / L$

$$
\left\langle\pi^{+} \pi^{-}\right| H_{W}\left|K^{0}\right\rangle \quad \propto \quad\left\langle\bar{d} u\left(t_{\pi_{1}}\right) \bar{u} d\left(t_{\pi_{2}}\right) H_{W}\left(t_{\mathrm{op}}\right) \bar{d} u\left(t_{K}\right)\right\rangle
$$

- Use boundary conditions on the quarks: $E_{\pi \pi}{ }^{\text {(gnd) }}=M_{K}$
- For $(\pi \pi)_{l=2}$ make $d$ anti-periodic
- For $(\pi \pi)_{l=0}$ use G-parity boundary conditions: $\underline{\text { arXiv:1908.08 }}$

# Calculation 

 of $A_{2}$
## $\Delta I=3 / 2$ - Continuum Results

(M. Lightman, E. Goode, T. Janowski)

- Use two large ensembles to remove $a^{2}$ error ( $m_{p}=135 \mathrm{MeV}$, $\mathrm{L}=5.4 \mathrm{fm}$ )
- $48^{3} \times 96,1 / a=1.73 \mathrm{GeV}$
- $64^{3} \times 128,1 / a=2.28 \mathrm{GeV}$

- Continuum results:
- $\operatorname{Re}\left(A_{2}\right)=1.50\left(0.04_{\text {stat }}\right)(0.14)_{\text {syst }} \times 10^{-8} \mathrm{GeV}$
- $\operatorname{Im}\left(A_{2}\right)=-6.99(0.20)_{\text {stat }}(0.84)_{\text {syst }} \times 10^{-13} \mathrm{GeV}$
- Experiment: $\operatorname{Re}\left(A_{2}\right)=1.479(4) 10^{-8} \mathrm{GeV}$
- $E_{\pi \pi} \rightarrow \delta_{2}=-11.6(2.5)(1.2)^{\circ}$
- [Phys. Rev. D91, 074502 (2015)]

## Calculation of $A_{0}$ and $\varepsilon^{\prime}$

## Overview of 2015 calculation (Chris Kelly and Daiqian Zhang)

- Use $32^{3} \times 64$ ensemble
$-1 / a=1.3784(68) \mathrm{GeV}, L=4.53 \mathrm{fm}$.
- G-parity boundary condition in 3 directions
- 216 configurations separated by 4 time units
- Essentially physical kinematics:
- $M_{\pi}=143.1(2.0)$
- $M_{K}=490.6(2.2) \mathrm{MeV}$
- $E_{\pi \pi}=498(11) \mathrm{MeV}$

## 2015 Results

[Phys. Rev. Lett. 115 (2015) 212001]

- $E_{\pi \pi}(499 \mathrm{MeV})$ determines $\delta_{0}$ :
- $I=0 \pi \pi$ phase shift: $\quad \delta_{0}=23.8(4.9)(2.2)^{\circ}$
- Dispersion theory result: $\delta_{0}=34^{\circ}$ [G. Colangelo, et al.]
- $\operatorname{Re}\left(\varepsilon^{\prime} / \varepsilon\right)=\left(1.38 \pm 5.15_{\text {stat }} \pm 4.59_{\text {sys }}\right) \times 10^{-4}$
- Expt.: ( $16.6 \pm 2.3$ ) x $10^{-4}$
- $2.1 \sigma$ difference
- Unanswered questions:
- Is this $2.1 \sigma$ difference real? $\rightarrow$ Reduce errors
- Why is $\delta_{0}$ so different from $\rightarrow$ Introduce more $\pi \pi$ operators the dispersive result? to distinguish excited states

## Extend and improve calculation

 (Chris Kelly and Tianle Wang)$\sqrt{ }-$ Increase statistics: $216 \rightarrow 1438$ configs.

- Reduce statistical errors
- Allow deeper study of systematic errors
$\checkmark$ - Study operators neglected in our NPR implementation
$\checkmark$ Use step-scaling to allow perturbative matching at a higher energy
$\checkmark$ Use an expanded set of $\pi \pi$ operators
- Use X-space NPR to cross charm threshold (Masaaki Tomii).

## Adding more statistics

- Increasing statistics: $216 \rightarrow 1438$ configs.
- $\pi \pi-\pi \pi$ correlator well-described by a single $\pi \pi$ state

$$
\begin{aligned}
- & \delta_{0}=23.8(4.9)(2.2)^{\circ} \rightarrow 19.1(2.5)(1.2)^{\circ} \\
& \chi^{2} / \operatorname{DoF}=1.6
\end{aligned}
$$

Mackenziefest - 11/07/2019

## Adding more $\pi \pi$ operators

- Adding a second $\sigma$-like ( $\bar{u} u+\overline{d d}$ ) operator reveals a second state!
- If only one state, $2 \times 2$ correlator matrix will have determinant $=0$. For $t_{f}-t_{i}=5$ :
$\operatorname{det}\left(\begin{array}{cc}\left\langle\pi \pi\left(t_{f}\right) \pi \pi\left(t_{i}\right)\right\rangle & \left\langle\pi \pi\left(t_{f}\right) \sigma\left(t_{i}\right)\right\rangle \\ \left\langle\sigma\left(t_{f}\right) \pi \pi\left(t_{i}\right)\right\rangle & \left\langle\sigma\left(t_{f}\right) \sigma\left(t_{i}\right)\right\rangle\end{array}\right)=0.439(50)$
- Add a third operator giving each pion a larger momentum: $p= \pm(3,1,1) \pi / L$
- Label operators as $\pi \pi(111), \sigma, \pi \pi(311)$
- Only 741 configurations with new operators

## $I=0 \pi \pi$ scattering with three operators

- Third $\pi \pi(311)$ operator not important.
- $\delta_{0}=31.7(6)^{\circ}$ vs $34^{\circ}$ prediction (5-15 fit, statistical errors only).

## $\mathrm{K} \rightarrow \pi \pi$ from 3-operator fits (case I)

- Fit using up to 3 operators and 3 states with energies and amplitudes from $\pi \pi$ scattering:

## $\mathrm{K} \rightarrow \pi \pi$ from 3-operator fits (case II)

- Fit using up to 3 operators and 3 states with energies and amplitudes from $\pi \pi$ scattering:

## $K \rightarrow \pi \pi$ matrix elements

- Compare old and new results (case I)

215 samples [2015]

741 samples [2019]

## Two data analysis challenges

- Auto-correlations - we must be careful that our errors are accurate
- We need estimates of goodness of fit ( $p$-values)
- Demonstrate that our fits describe the data.
- Decide if alternative fits used to estimate systematic errors are plausible.
- However, our lattice QCD p-values are traditionally unreasonably small!

## Auto-correlations

- Our measurements are made every 4 MD time units and are mildly correlated.
- While we have $\mathrm{N}=741$ configurations, the covariance matrix for three operators and $t=5-15$ time slices is $66 \times 66$ !
- Noise grows as we bin the data and have fewer samples to measure the fluctuations.
- Solved by the blocked jackknife method:
- Identify $N / B$ blocks of size $B$.
- Sequentially remove each block and analyze the remaining N -B (not N/B-1) samples

## I=0 $\pi \pi$ two-point function fit errors

Binned data errors

Binned scrambled data errors

## Poor $p$-values

- We obtain $p$-values of $0.1-0.2$ for most "best fits"!
- This is often caused by ignoring fluctuations in the covariance matrix (Tanmoy Bhattacharya).
- Including covariance matrix fluctuations broadens the $\chi^{2}$ distribution into the Hotelling $T^{2}$ distribution (related to $F$ distrib.).

## Hotelling $T^{2}$ is insufficient

- Hotelling assumes that the data (not their averages) are Gaussian and uncorrelated.
- Both are not true for our case.
- Use a bootstrap analysis to determine the correct generalized $\chi^{2}$ distribution from the data. (C. Kelly)

## $q^{2}$ distribution

- Define $q^{2}=\sum_{t, t=t_{\min }}^{t_{\text {max }}}\left[\bar{v}_{t}-f(t, \vec{p})\right]\left[C^{-1}\right]_{t^{\prime}}\left[\overline{\bar{t}}_{t^{\prime}}-f\left(t^{\prime}, \vec{p}\right)\right]$
where $\quad \mathrm{C}_{\mathrm{tt}}{ }^{\prime}=\frac{1}{\mathrm{~N}(\mathrm{~N}-1)} \sum_{\mathrm{i}=1}^{\mathrm{N}}\left[\mathrm{v}_{\mathrm{i}, \mathrm{t}}-\overline{\mathrm{v}}_{\mathrm{t}}\right]\left[\mathrm{v}_{\mathrm{i}, \mathrm{t}^{\prime}}-\overline{\mathrm{v}}_{\mathrm{t}^{\prime}}\right]$
- Find $P\left(q^{2}\right)$ where

$$
\int_{0}^{\infty} \mathrm{P}\left(\mathrm{q}^{2}\right) \mathrm{dq}^{2}=1 \quad \text { and } \quad \mathrm{p}_{\text {int }}\left(\mathrm{q}^{2}\right)=\int_{\mathrm{q}^{2}}^{\infty} \mathrm{P}\left(\mathrm{q}^{2}\right) \mathrm{dq} \mathrm{q}^{2}
$$

- Here $p_{\text {int }}\left(q^{2}\right)$ gives the " $p$-value"

## Find $q^{2}$ distribution from the data

 (Chris Kelly)- Start with the original ensemble $\left\{v_{i t}\right\}_{1 \leq i \leq N}$
- Draw $N$ values from this set (allowing the same value to be drawn multiple times).
- Create $N_{\text {boot }}$ such ensembles of $N$ values: $\left\{b_{i t}{ }^{\alpha}\right\}_{1 \leq i \leq N}$ where $1 \leq \alpha \leq N_{\text {boot }}$
- Recenter these ensembles so $f(t, \vec{p})$ will fit the average over boot strap ensembles perfectly:

$$
b_{i, t}^{\alpha} \rightarrow \tilde{b}_{i, t}^{\alpha}=b_{i, t}^{\alpha}-\bar{v}_{t}+\mathrm{f}(\mathrm{t}, \overrightarrow{\mathrm{p}})
$$

- Here the parameters $\vec{p}$ fit the average data $\bar{v}_{t}$

## $q^{2}$ distribution

- $\tilde{\mathrm{b}}_{i, \mathrm{t}}^{\alpha}$ has the fluctuation in the population but is fit perfectly by $f(t, \vec{p})$

$$
\mathrm{b}_{\mathrm{i}, \mathrm{t}}^{\alpha} \rightarrow \tilde{\mathrm{b}}_{\mathrm{i}, \mathrm{t}}^{\alpha}=\mathrm{b}_{\mathrm{i}, \mathrm{t}}^{\alpha}-\overline{\mathrm{v}}_{\mathrm{t}}+\mathrm{f}(\mathrm{t}, \overrightarrow{\mathrm{p}}) \quad \begin{gathered}
\text { Fit to } \\
\text { ensemble } \alpha
\end{gathered}
$$

$$
\begin{aligned}
& \text { Thus } \\
& \left.\left.\left(\mathrm{q}^{2}\right)^{\alpha}=\sum_{\mathrm{t}, \mathrm{t}=\mathrm{t}_{\text {min }}}^{\mathrm{t}_{\text {max }}}\left[\tilde{\overline{\mathrm{b}}}_{\mathrm{t}}^{\alpha}-\mathrm{f}\left(\mathrm{t}, \overrightarrow{\mathrm{P}}^{\alpha}\right)\right]^{2}\right]\left(\mathrm{C}^{\alpha}\right)^{-1}\right]_{\mathrm{tt}^{\prime}}\left[\tilde{\overline{\mathrm{b}}}_{\mathrm{t}^{\prime}}-\mathrm{f}\left(\mathrm{t}^{\prime}, \overrightarrow{\mathrm{p}}^{\alpha}\right)\right]
\end{aligned}
$$

will obey (and give) the correct $q^{2}$ distribution.

- $p\left(q^{2}\right)=N\left(q^{2}\right) / N_{\text {boot }}$ where $N\left(q^{2}\right)$ is the number of bootstrap ensembles with $\left(q^{2}\right)^{\alpha}>q^{2}$.
- Now $p$-values can be computed for any definition of $q^{2}$ including for uncorrelated fits!

## $K \rightarrow \pi \pi$ calculation (2019)

- Calculation of $K \rightarrow \pi \pi$ decay substantially improved over 2015 result.
- $216 \rightarrow 741$ configurations.
- Three $\pi \pi$ interpolating operators: discriminate between ground and excited states $\rightarrow \delta_{0}\left(E=M_{k}\right)=31.7(6)^{\circ}$
- Errors reduced by using correlated fits.
- Bootstrap-determined $q^{2}$ distribution gives correct $p$-values. [ $p=0.261$ (BS) vs $\left.0.037\left(\chi^{2}\right)\right]$
- Results available soon.

## Thanks!

- Precision measurement + lattice QCD is a long-term direction of great promise.
- Paul is a leading contributor
- Important new results lie ahead.
- Importance of Paul's national leadership is hard to overstate:

$>$ USQCD hardware has enabled frontier calculations
> Many careers advanced by USQCD projects.
$>$ Collaborative good will and combined strengths of USQCD attract new talent and enhanced funding!
