

Optimizing Low Latency
LIGO-Virgo Localization

Hsin-Yu Chen, Daniel Holz

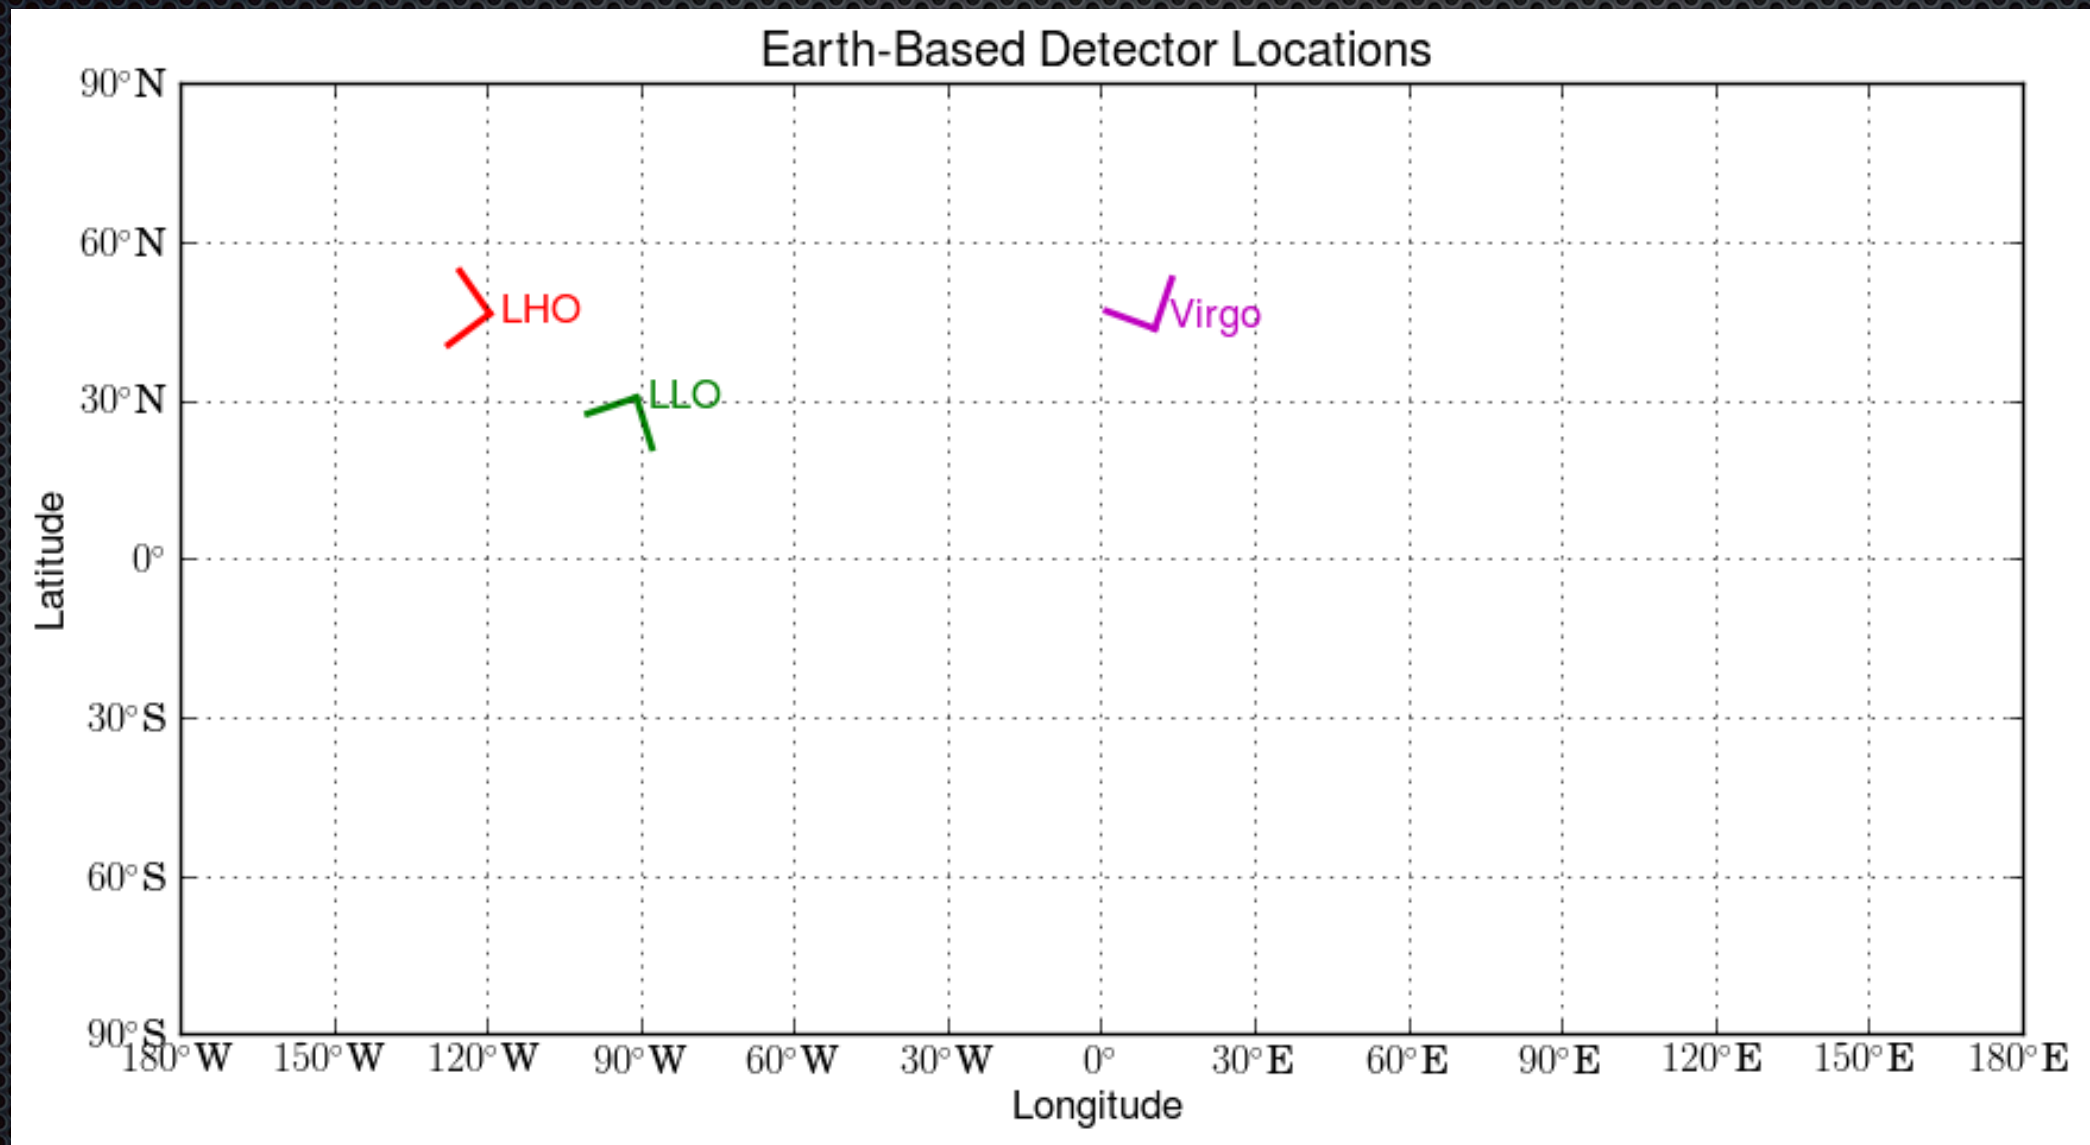

DES Chicagoland Meeting, Dec. 2014

GW multi-messenger Astronomy

- Advanced LIGO online: Fall 2015
- Most promising source: Compact binary coalescence
- Possible EM counterpart for NSNS or NSBH merger:
 - Short gamma-ray burst (seconds)
 - Kilonovae [optical or IR] (hours to days)
 - Radio Afterglow (months)

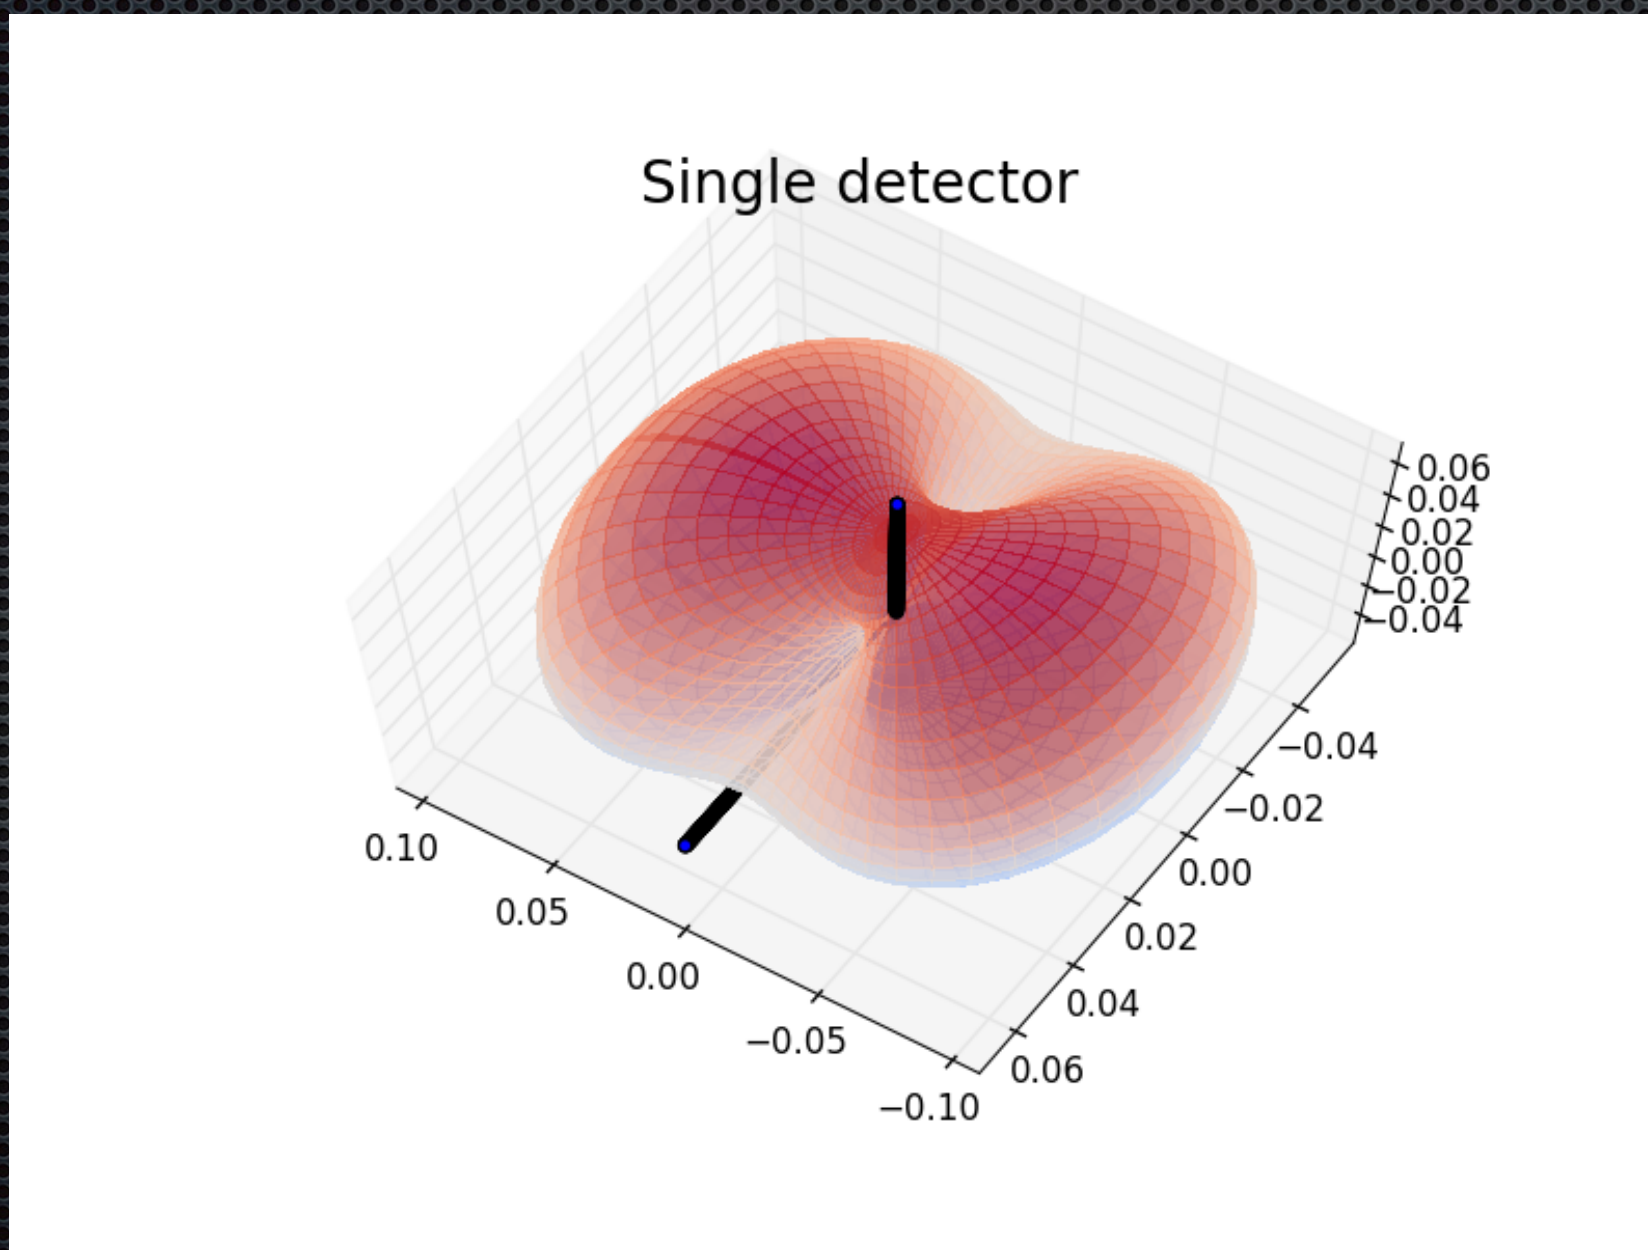

Low latency LIGO-Virgo Localization

Timing Triangulation

Aug-Jan: Daytime, kilonova

Feb -Jul: Nighttime, precursor

Effective Area=Area/confidence

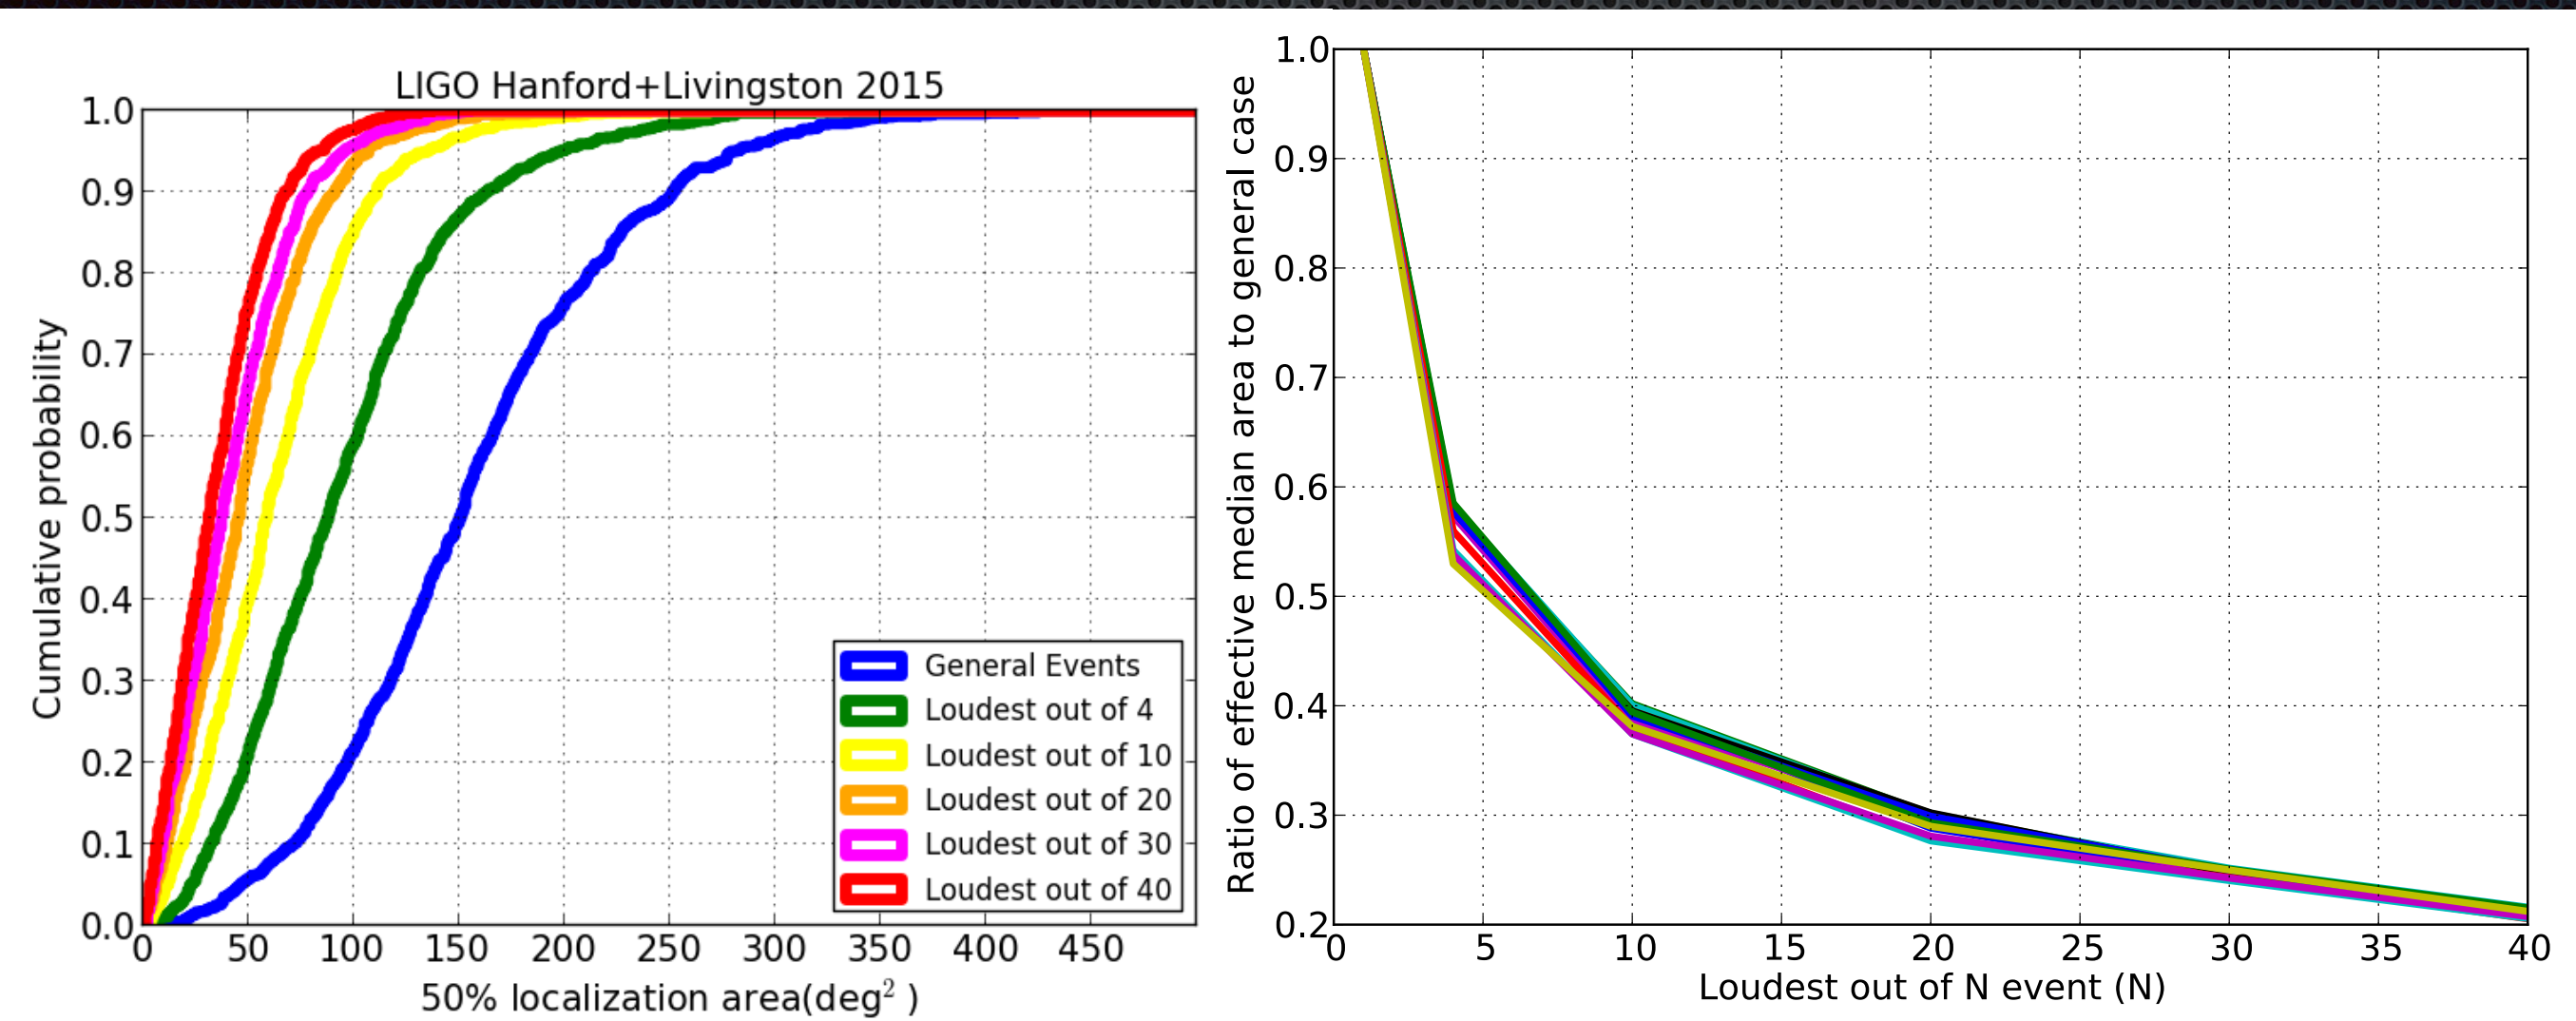

Effective Area=Area/confidence

- Efficiently cover the area

Localization Improvement from the Loudest Event

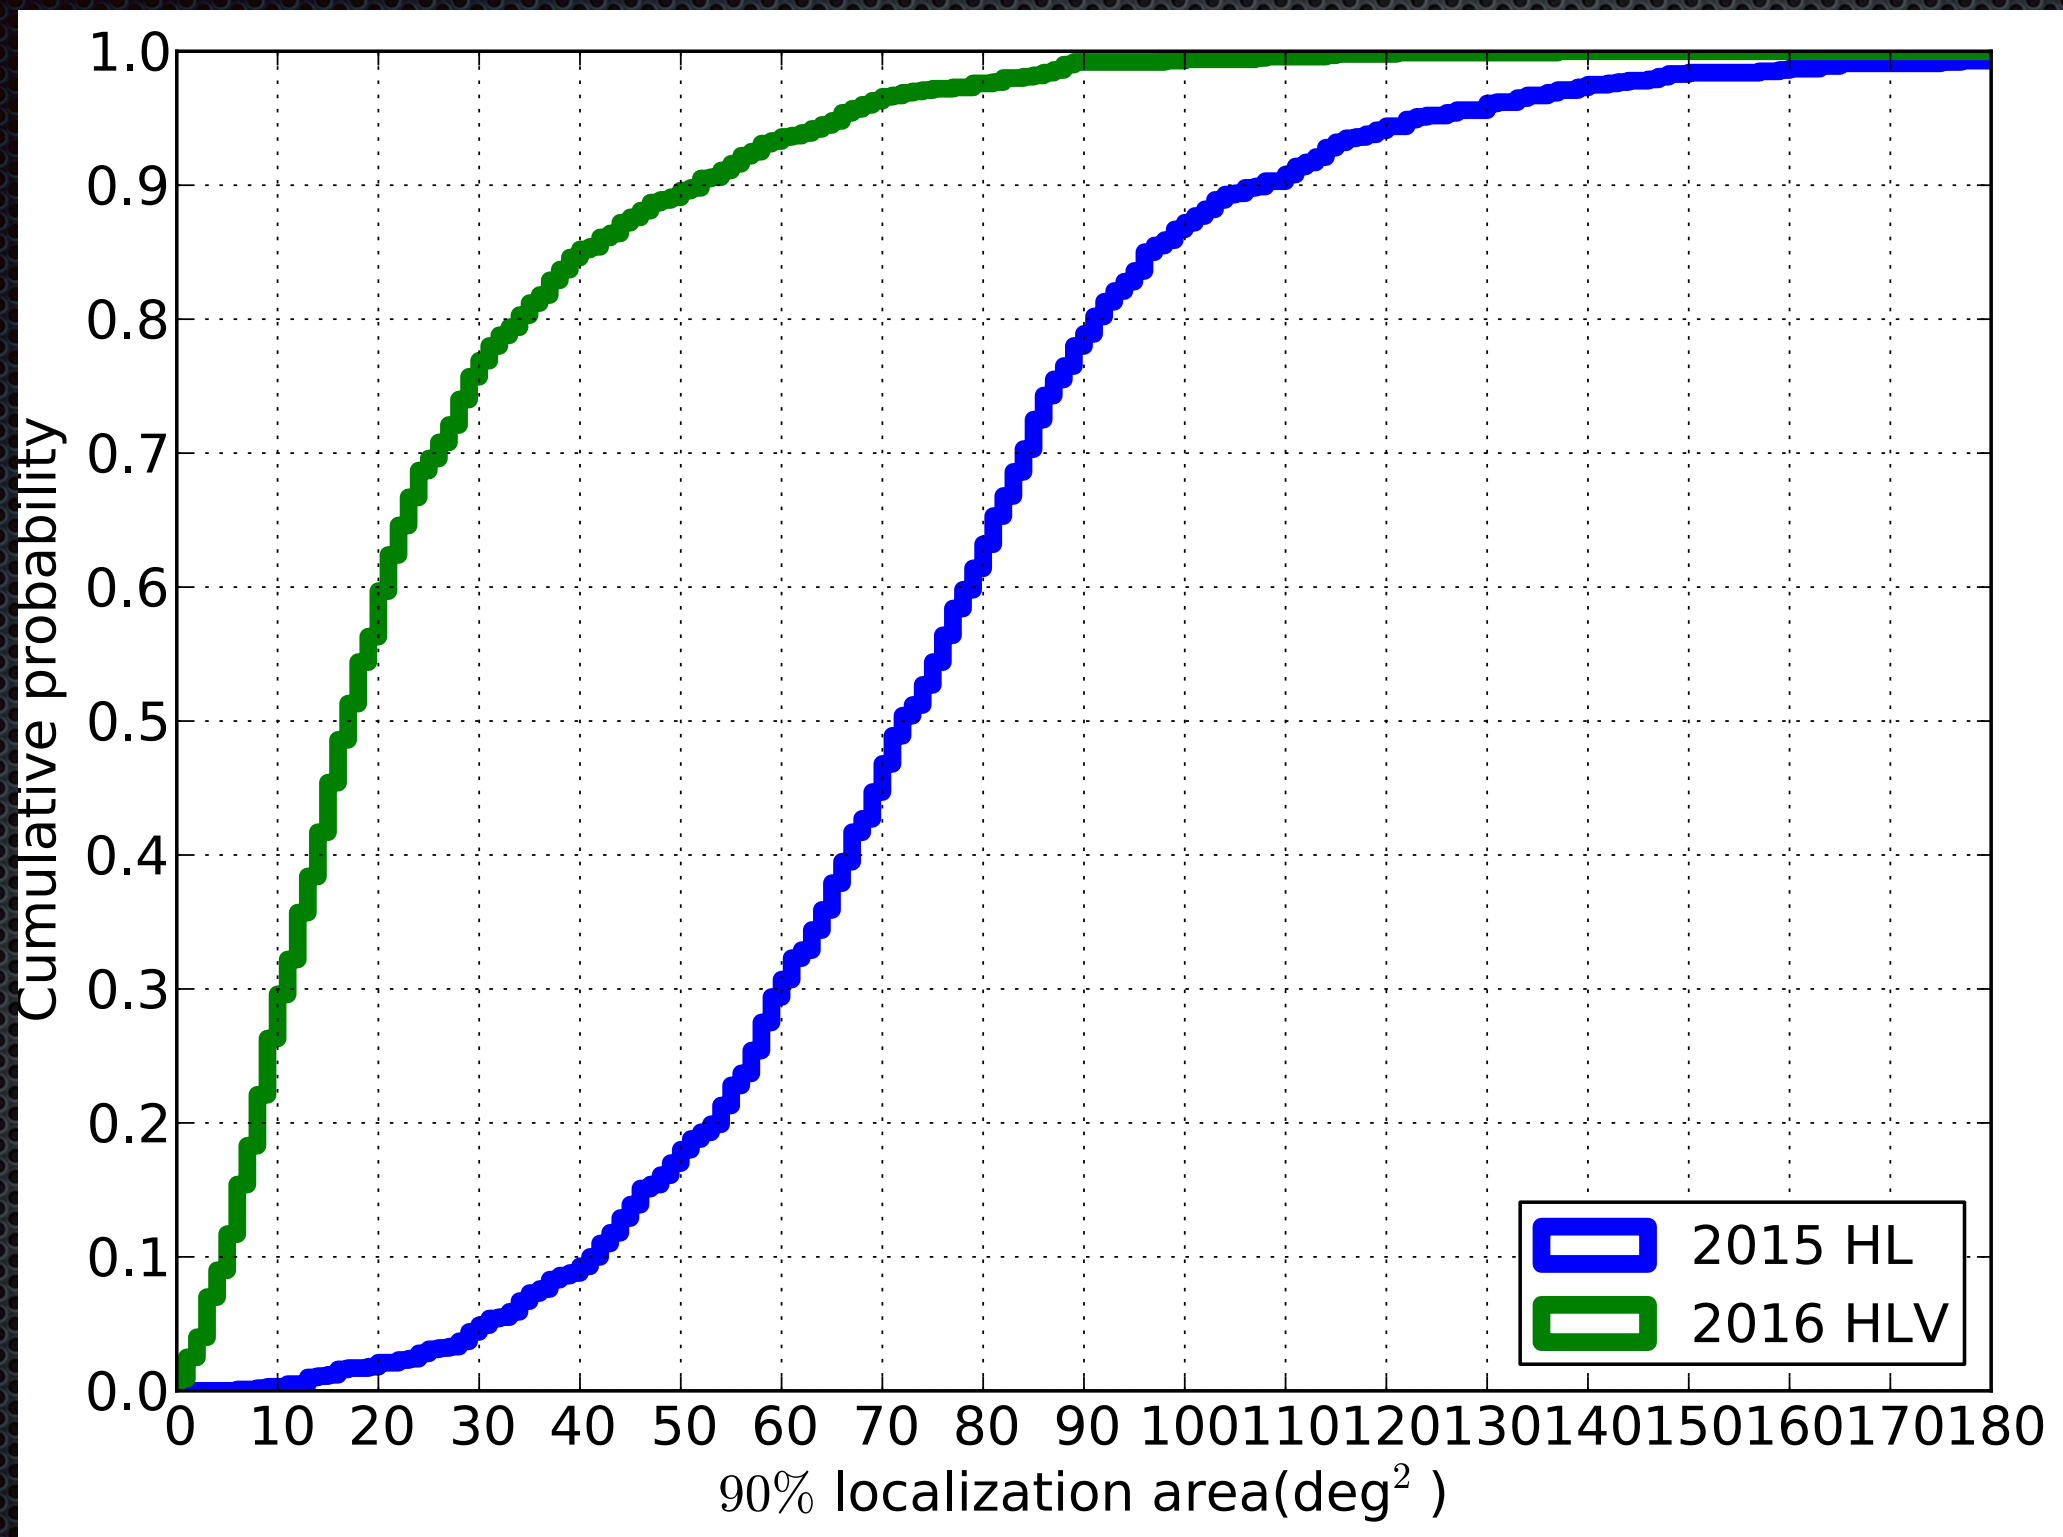

Localization Improvement from the Loudest Event

- Carefully select event

Fermi GBM-GW Joint Detection

Sub-second Localization

- Sky prior $f(\theta, \phi)$
- Only two input: arrival time and SNR
- Utilize the SNR ratio: $\rho \sim \frac{\mathcal{M}^{5/6}}{D} (\Omega(\theta, \phi, \iota, \psi) I_7)^{1/2}$

$$\frac{\rho_i}{\rho_j}(\theta, \phi, \iota, \psi) = \left(\frac{\Omega_i(\theta, \phi, \iota, \psi) I_{7,i}}{\Omega_j(\theta, \phi, \iota, \psi) I_{7,j}} \right)^{1/2}$$

- Pre-grid and pre-calculate: table lookups and compare
