

Cluster Cosmology with the South Pole Telescope

Bradford Benson
(Fermilab, U. Chicago)

SZ Cluster Surveys: Mass vs Redshift

	Area (deg ²)	Depth (uK-arcmin)	N_{clusters}
Planck	All-sky	~45	861
SPT	2500	17	516
ACT	950	23-40	91

First SZ-discovered cluster was in 2008 (Staniszewski et al); 6 years later there are > 1300 SZ-identified clusters!

Dark Energy and Cluster Cosmology

- Abundance of clusters is sensitive to the **dark energy equation of state, $w = p / \rho$**
- If dark energy was due to a cosmological constant then $w = -1$

Cluster Abundance: dN/dz

$$\frac{dN}{d\Omega dz} = n(z) \frac{dV}{d\Omega dz}$$

Depends on:

Matter Power Spectrum, σ_8
Growth Rate of Structure, $D(z)$

Depends on:

Rate of Expansion, $H(z)$

SPT Significance as a Mass Proxy

From Simulations by Laurie Shaw

- The challenge for any cluster survey is to link cluster “observable” to cluster mass

- ***The SZ flux is expected to be a low-scatter observable***

(Kravstov 2006, Fabjan 2011, Battaglia 2012)

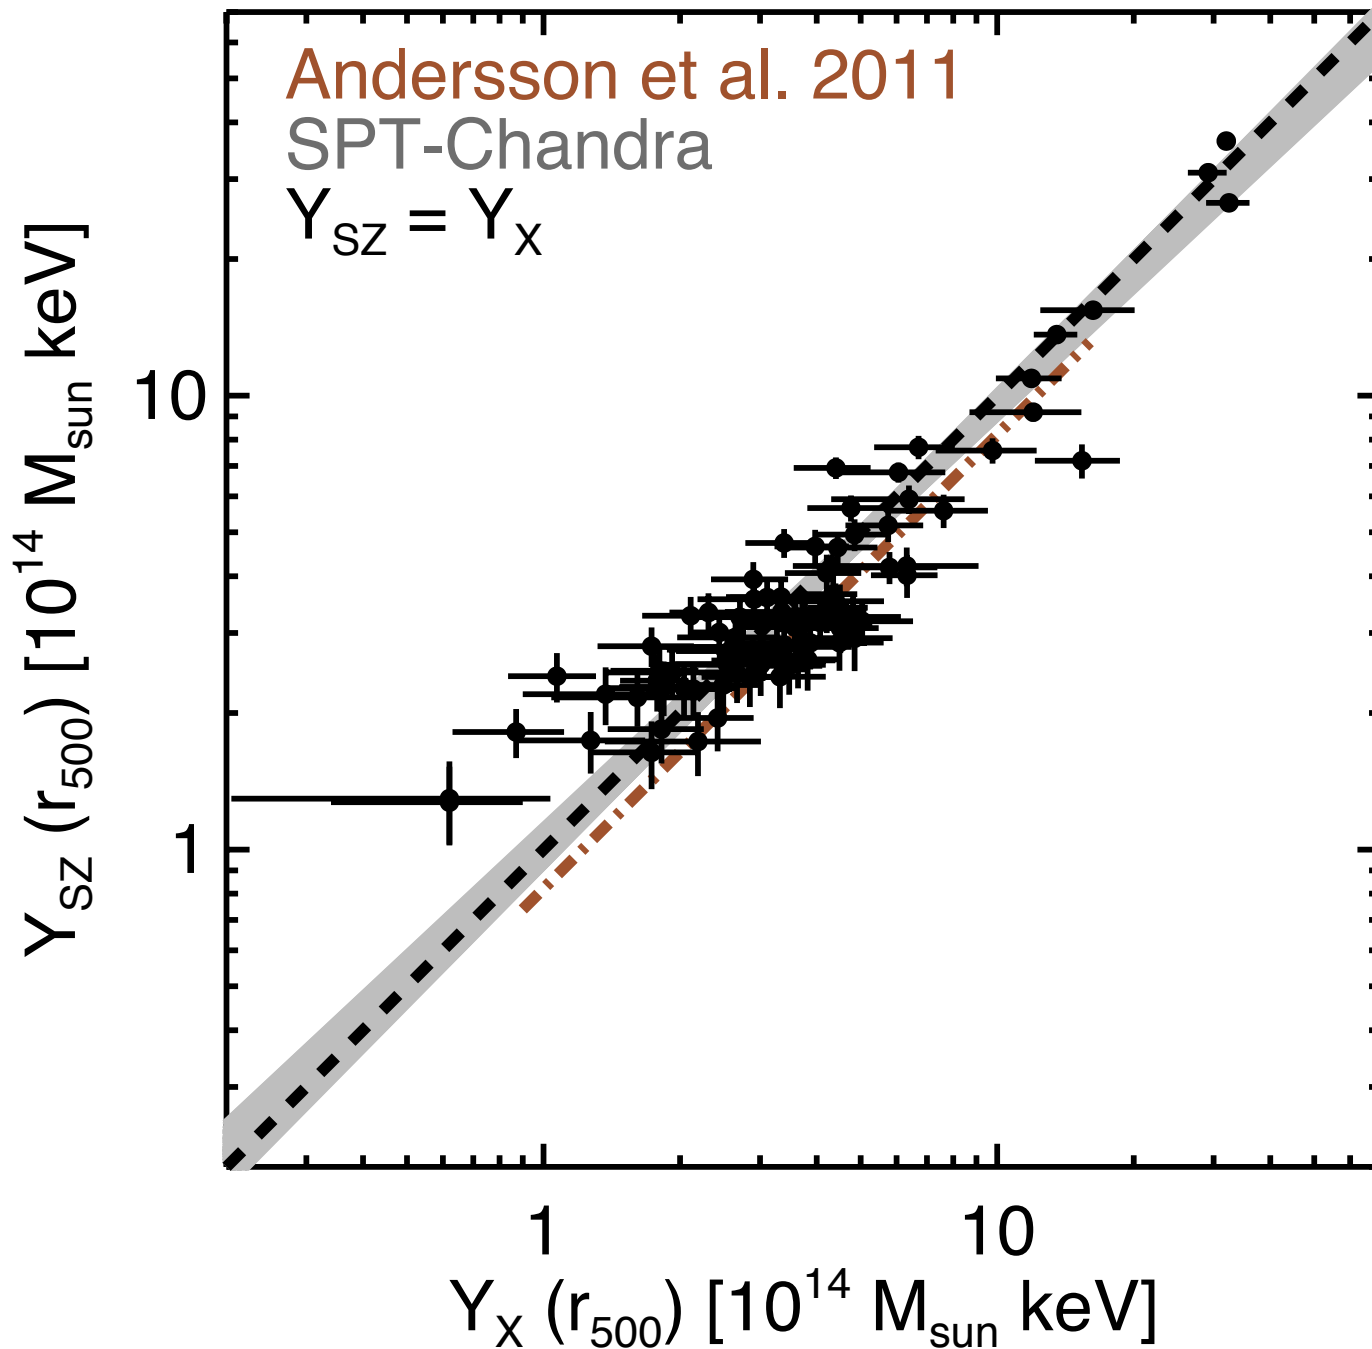

- S/N in filtered SPT map is a low-scatter mass proxy (Vanderlinde+10)

- **Scatter in $\ln(M)$**

- 7% given Y_{sz}, Y_x
- 12% given SPT S/N
- ~25% given X-ray L_x
- ~30% given Richness

$Y_{SZ}-Y_X$ Relation:

Fit using 83 Clusters with Chandra X-ray Observations

SZ vs X-ray measure of “Compton” Y parameter (density x temperature)

- 1:1 relation with no tilt
- No redshift-evolution
- Low-scatter ($\sim 10\%$)

Cosmological Analysis:

Combine X-ray Observables with SPT Cluster Survey

Use Markov-Chain Monte Carlo (MCMC) method to vary cosmology and cluster observable-mass relation simultaneously, while accounting for SZ selection in a self-consistent way

6 Cosmology Parameters (plus extension parameters)

- Λ CDM Cosmology
 - $\Omega_m h^2, \Omega_b h^2, A_s, n_s, \theta_s$
- Extension Cosmology
 - $w, \Sigma m_\nu, f_{NL}, N_{eff}$

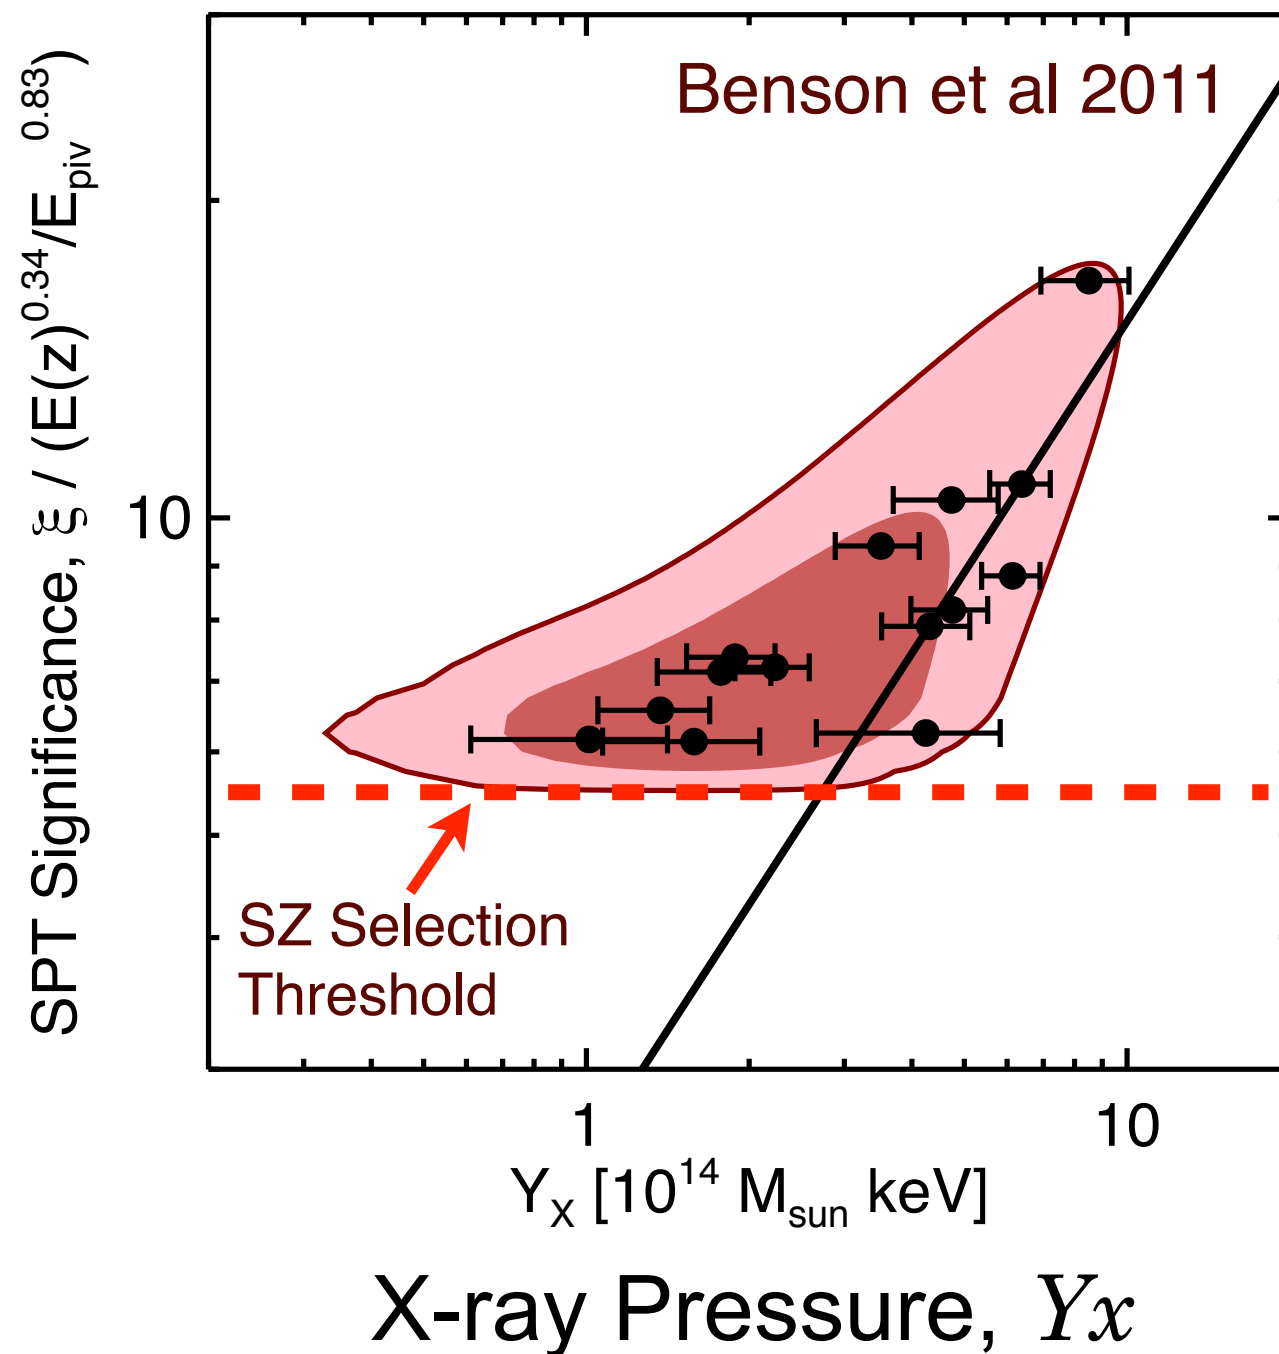

9 Scaling Relation Parameters

- X-ray (Y_x-M) and SZ ($\zeta-M$) relations (4 and 5 parameters):
 - A) normalization,
 - B) slope,
 - C) redshift evolution,
 - D) scatter,
 - F) correlated scatter

SPT Significance-Mass Calibration

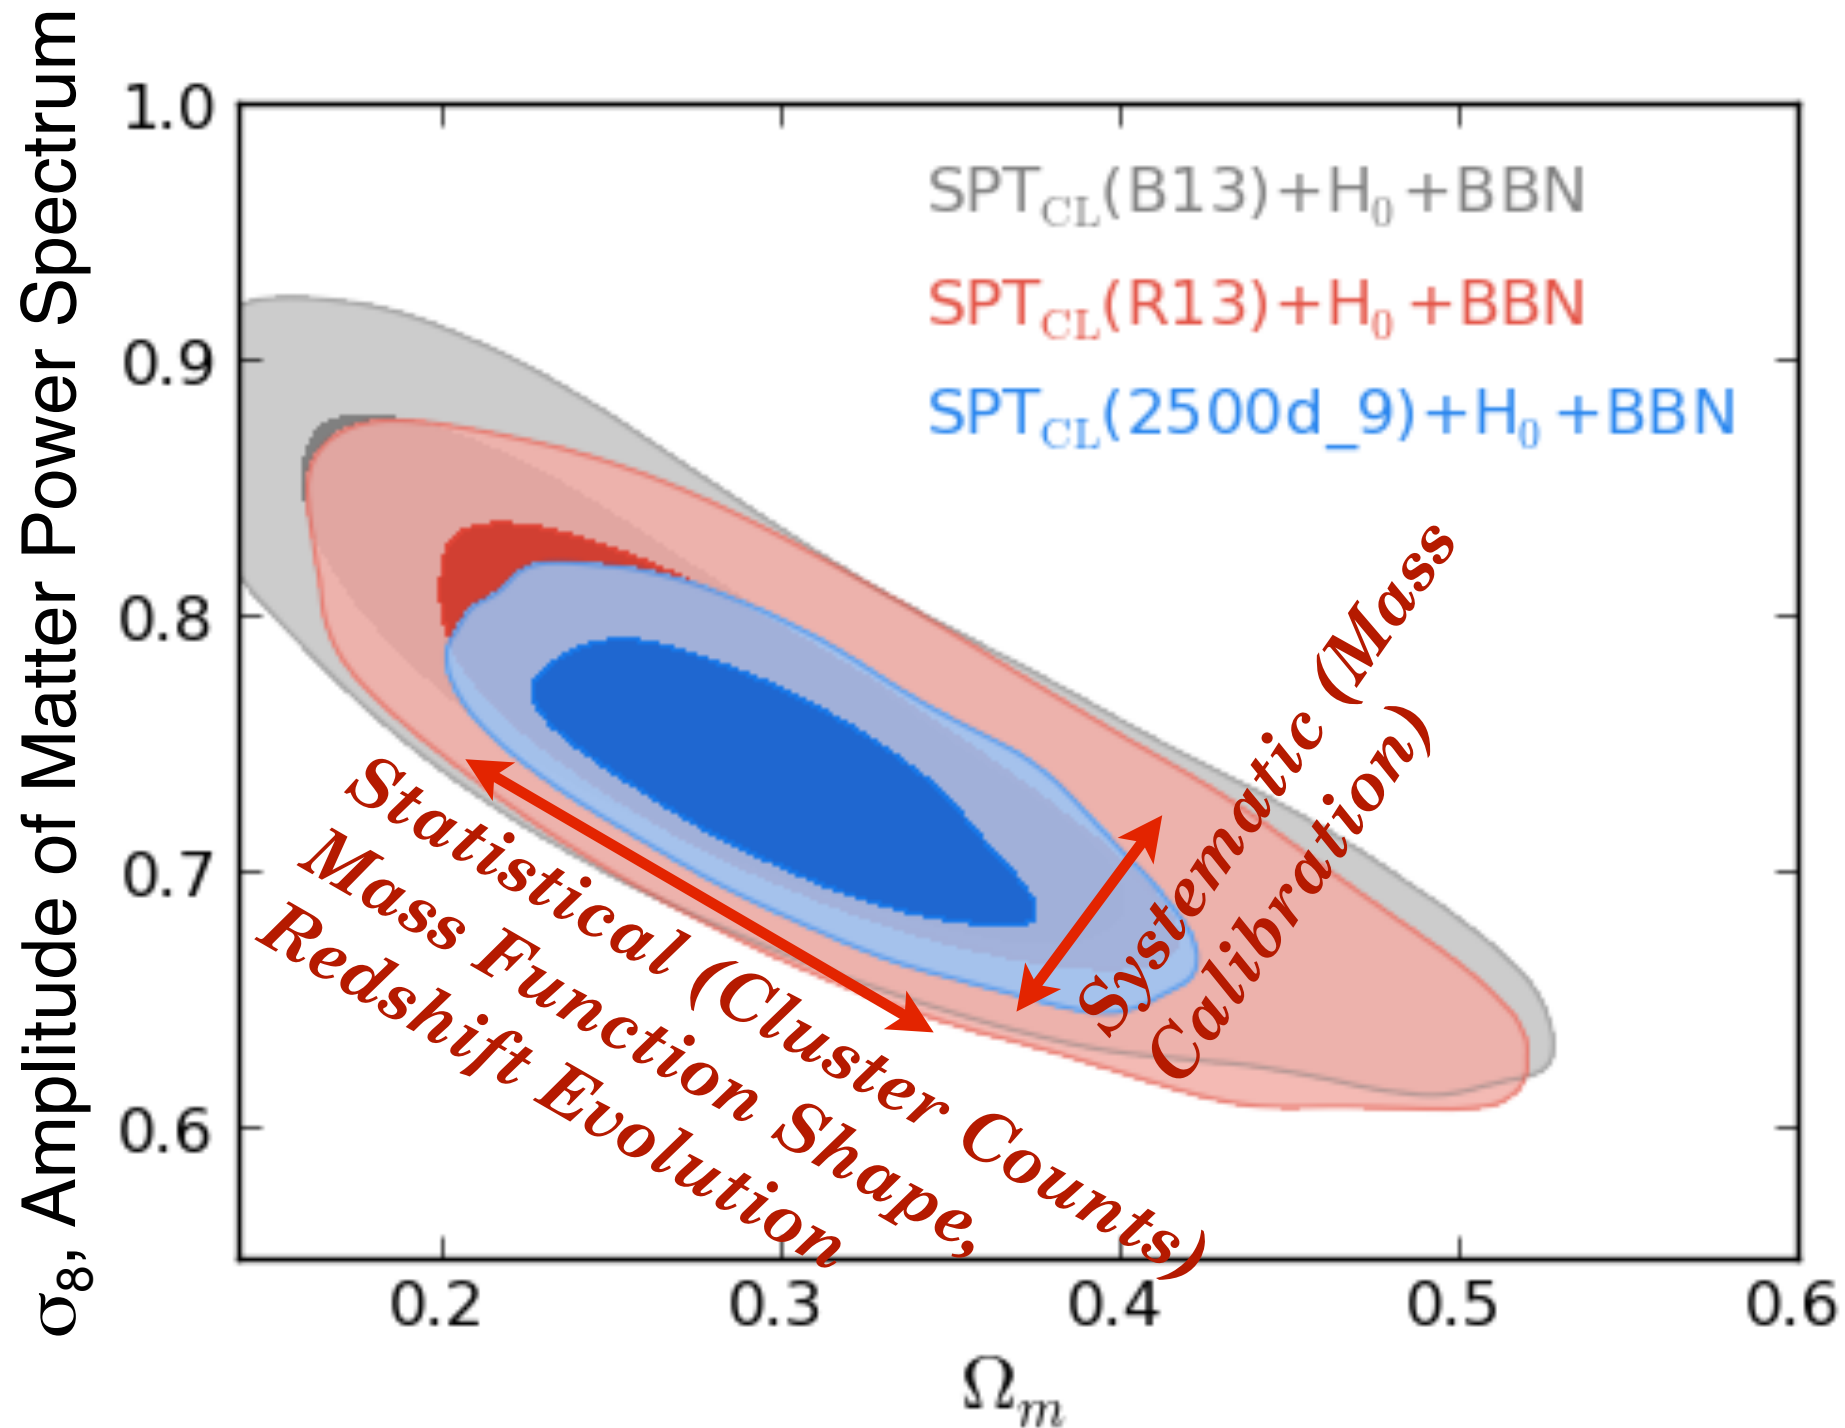

Use X-ray (Y_x - M) relation to calibrate SPT significance-mass relation:

- *X-ray observations calibrate slope, scatter, redshift evolution*
- *Weak Lensing calibrates mass normalization (~10-15% accuracy)*

Λ CDM Constraints:

SPT data using Vikhlinin+09 Y_x mass calibration

CMB Constraints on σ_8, Ω_m

Small but important shift in σ_8 between WMAP and Planck

- Number of clusters goes like $(\sigma_8)^{10}$
- Planck cosmology predicts ~ 2 - 3 x more clusters than WMAP

Cluster counts $\sim (\sigma_8)^{10}$

Yx-M Weak Lensing (WL) Calibration: Updating calibration to new Hoekstra+14 calibration

$M(\text{WL})-M(\text{Yx})$

- Updated Yx-M calibration using weak-lensing (WL) masses from Hoekstra+14
- Multiply Vikhlinin+09 Yx-masses by:
 - Hoekstra+12: 1.03 ± 0.15
 - Hoekstra+14: 1.15 ± 0.16

$$\mathbf{M(\text{WL, Hoekstra+14})} \\ \mathbf{= (1.15 \pm 0.16) M(\text{Yx})}$$

- **Caveat:** Reasonable WL people (e.g., Hoekstra, von der Linden) still have $\sim 10\text{-}15\%$ offsets in mass estimates even using the same WL / shear data

Λ CDM Constraints:

Using Hoekstra et al. 2014 Weak Lensing calibration

- Weak lensing (WL) is used to calibrate absolute mass scale
- WL techniques and measurements have improved quickly
- Current measurements indicate a 15% increase in mass calibration from Yx-calibration

Λ CDM Constraints: CMB vs Clusters

Updated to Hoekstra et al. 2014 calibration

- **Planck CMB** and **SPT clusters** are statistically consistent
- Relatively good agreement between SPT clusters with “**Weighing the Giants**” (Mantz et al. 2014), based on Rosat all-sky survey

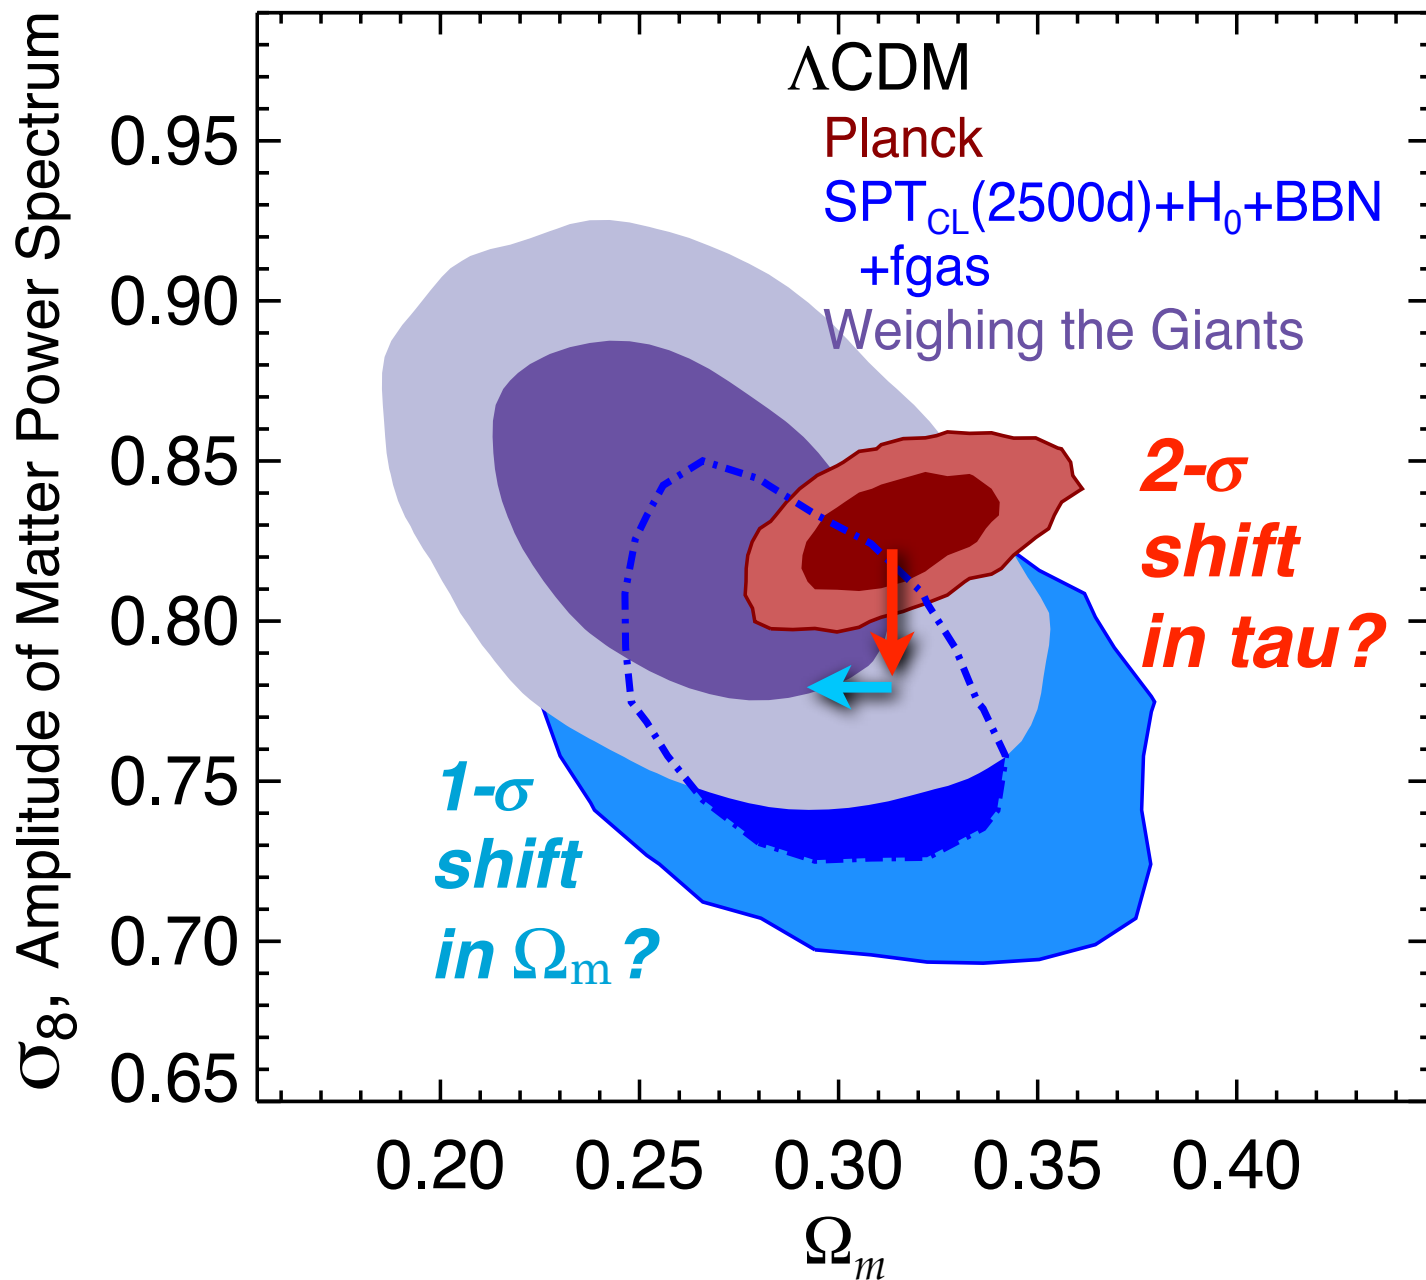

SPT_{CL}+H₀+BBN+fgas

$$\sigma_8 = 0.783 \pm 0.040$$

$$\Omega_m = 0.293 \pm 0.034$$

Λ CDM Constraints: CMB vs Clusters

How will this change with Planck-CMB 2014 release?

New Planck papers Dec. 22, 2014!

What to look for (aka rumors) regarding σ_8, Ω_m :

1) Reionization optical depth will decrease by $>1\sigma$

- Planck dust measurements impact CMB constraints: $\delta(\tau) \sim \delta(\sigma_8)$*

2) Movement back towards WMAP cosmology

- Planck 220 GHz had odd pull on Ω_m constraint (Spergel et al. 2014)*

3) Calibration Offset between WMAP and Planck

- 5-sigma (2% power) discrepant between WMAP, Planck*

Λ CDM Constraints: CMB vs Clusters

How will this change with Planck-CMB 2014 release?

New Planck papers Dec. 22, 2014!

What to look for (aka rumors) regarding σ_8, Ω_m :

1) Reionization optical depth

Planck

will decrease

• Planck dust measurements impact CMB constraints: $\delta(\tau) \sim \delta(\sigma_8)$

2) Movement back towards

WMAP

• Planck 220 GHz had odd pull on Ω_m

constraints (Speiser et al. 2014)

3) Calibration Offset between

WMAP and Planck

• 5-sigma (2% power) discrepant between WMAP, Planck

stayed the same!?!

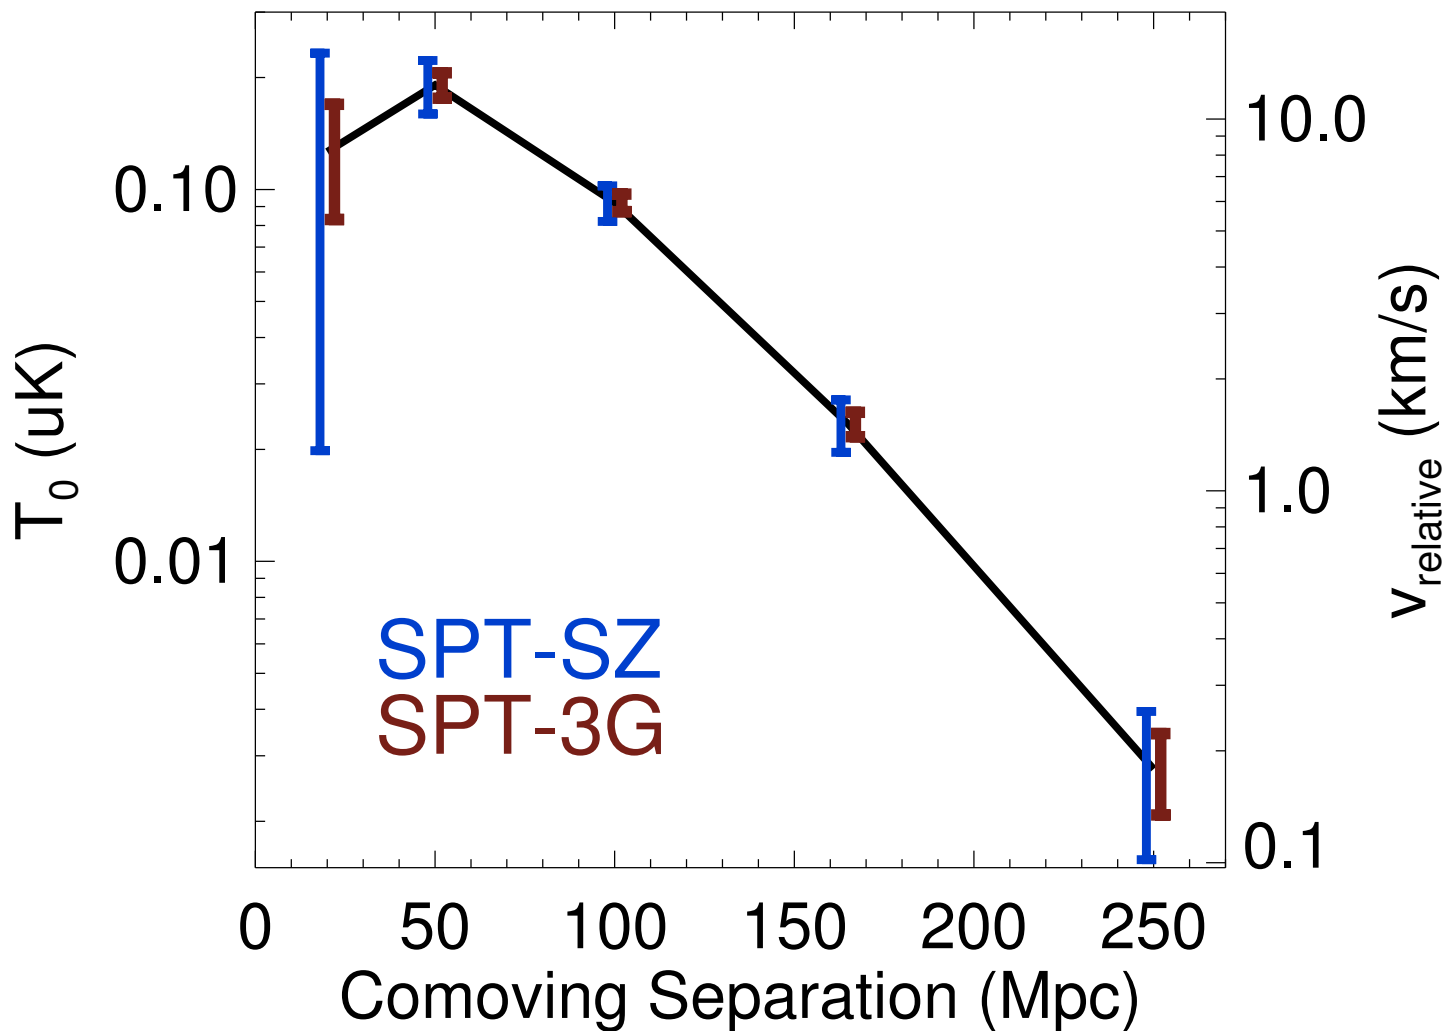

Joint DES, SPT Cosmology: Cluster Abundance

- Same basic likelihood formalism can be applied to joint DES +SPT cluster cosmology
 - *Select on DES richness, SPT is the “follow-up” observable*
- SPT effectively provides the scatter calibration for DES
 - *In Rozo+09 (MaxBCG), scatter prior limited σ_8 to a 4% constraint*
- Synergies between DES, SPT surveys is most evident in growth factor constraint gamma

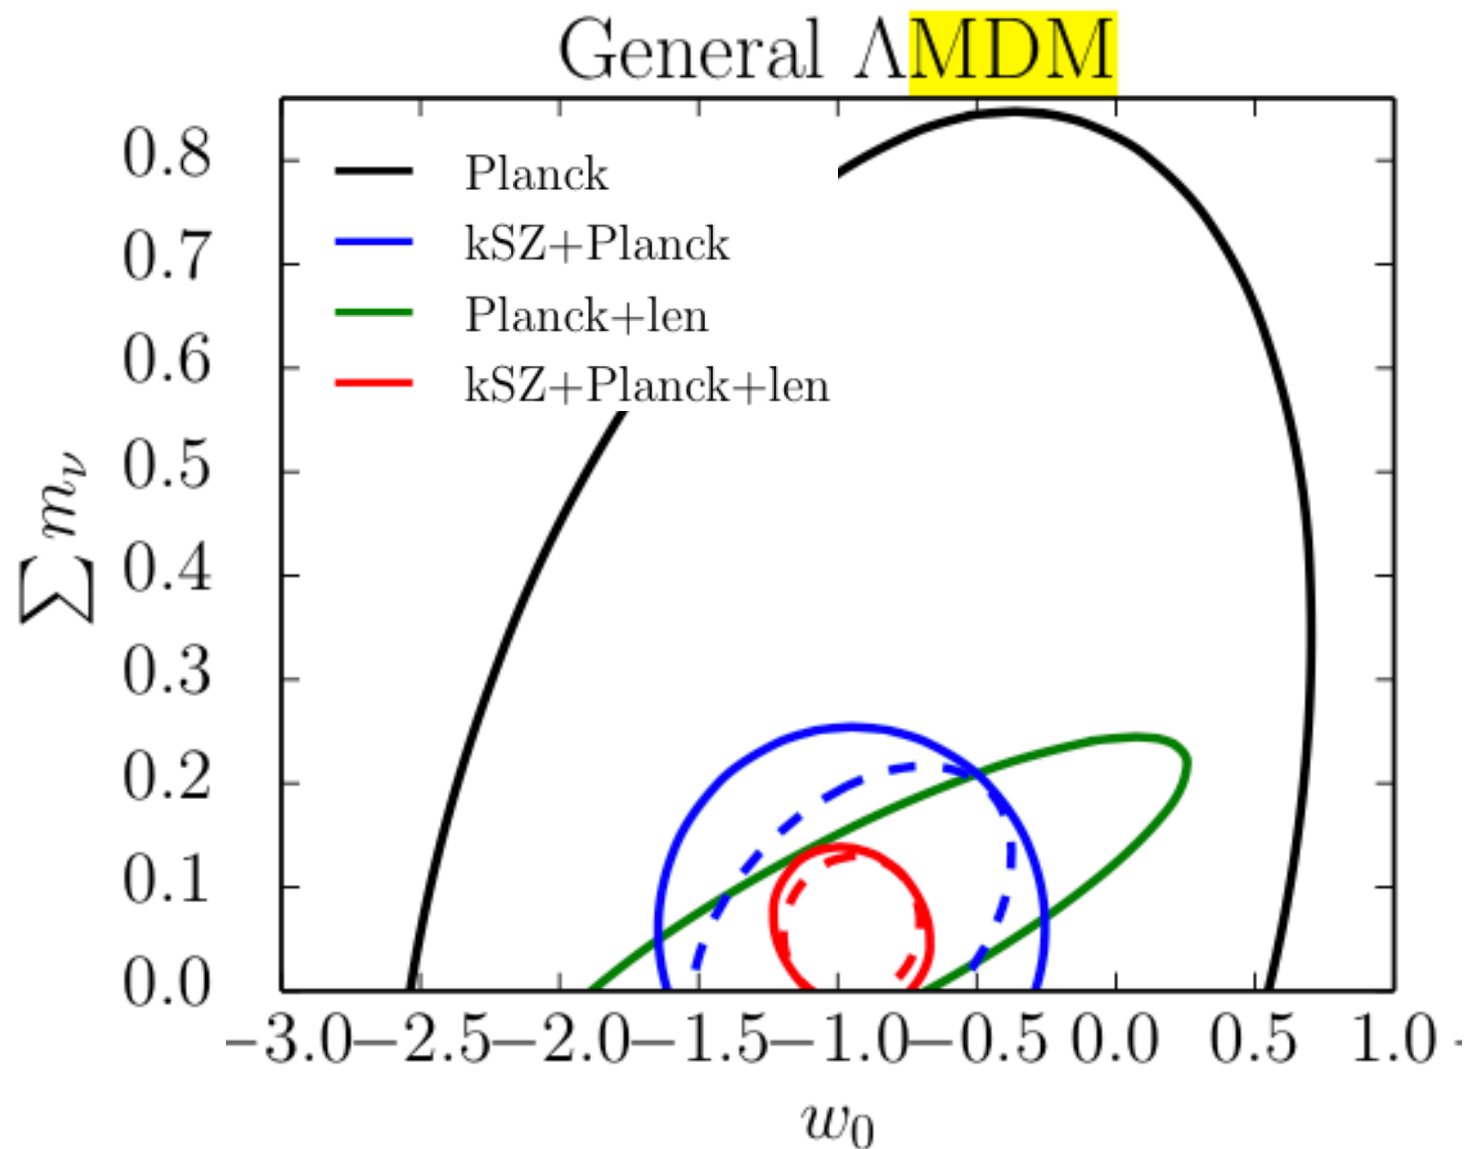

$$\frac{d \ln D}{d \ln a} \simeq \Omega_m(a)^\gamma$$

Joint DES, SPT Cosmology: kinematic Sunyaev-Zel'dovich (kSZ) Pairwise

- kSZ effect imprints peculiar velocity of cluster in CMB (velocity relative to CMB rest frame)
 - *Clusters are test particles which probe the large scale gravitational potential by measuring their “pull” on each other*
- Recently detected at 3-sigma using ACT+SDSS (Hand+12)
- SPT-SZ(3G)+DES expects to detect kSZ at 13 (30) sigma (Keisler+12)

Joint DES, SPT Cosmology: kinematic Sunyaev-Zel'dovich (kSZ) Pairwise

- kSZ potentially powerful probe to break degeneracy between dark energy (“ w ”) and growth (“ γ ”) constraints
- Interesting constraints on the sum of the neutrino masses
 - *A StageIV CMB experiment kSZ constrains $\sigma(\Sigma m_\nu) \sim 30$ meV, comparable to LSST, DESI surveys*

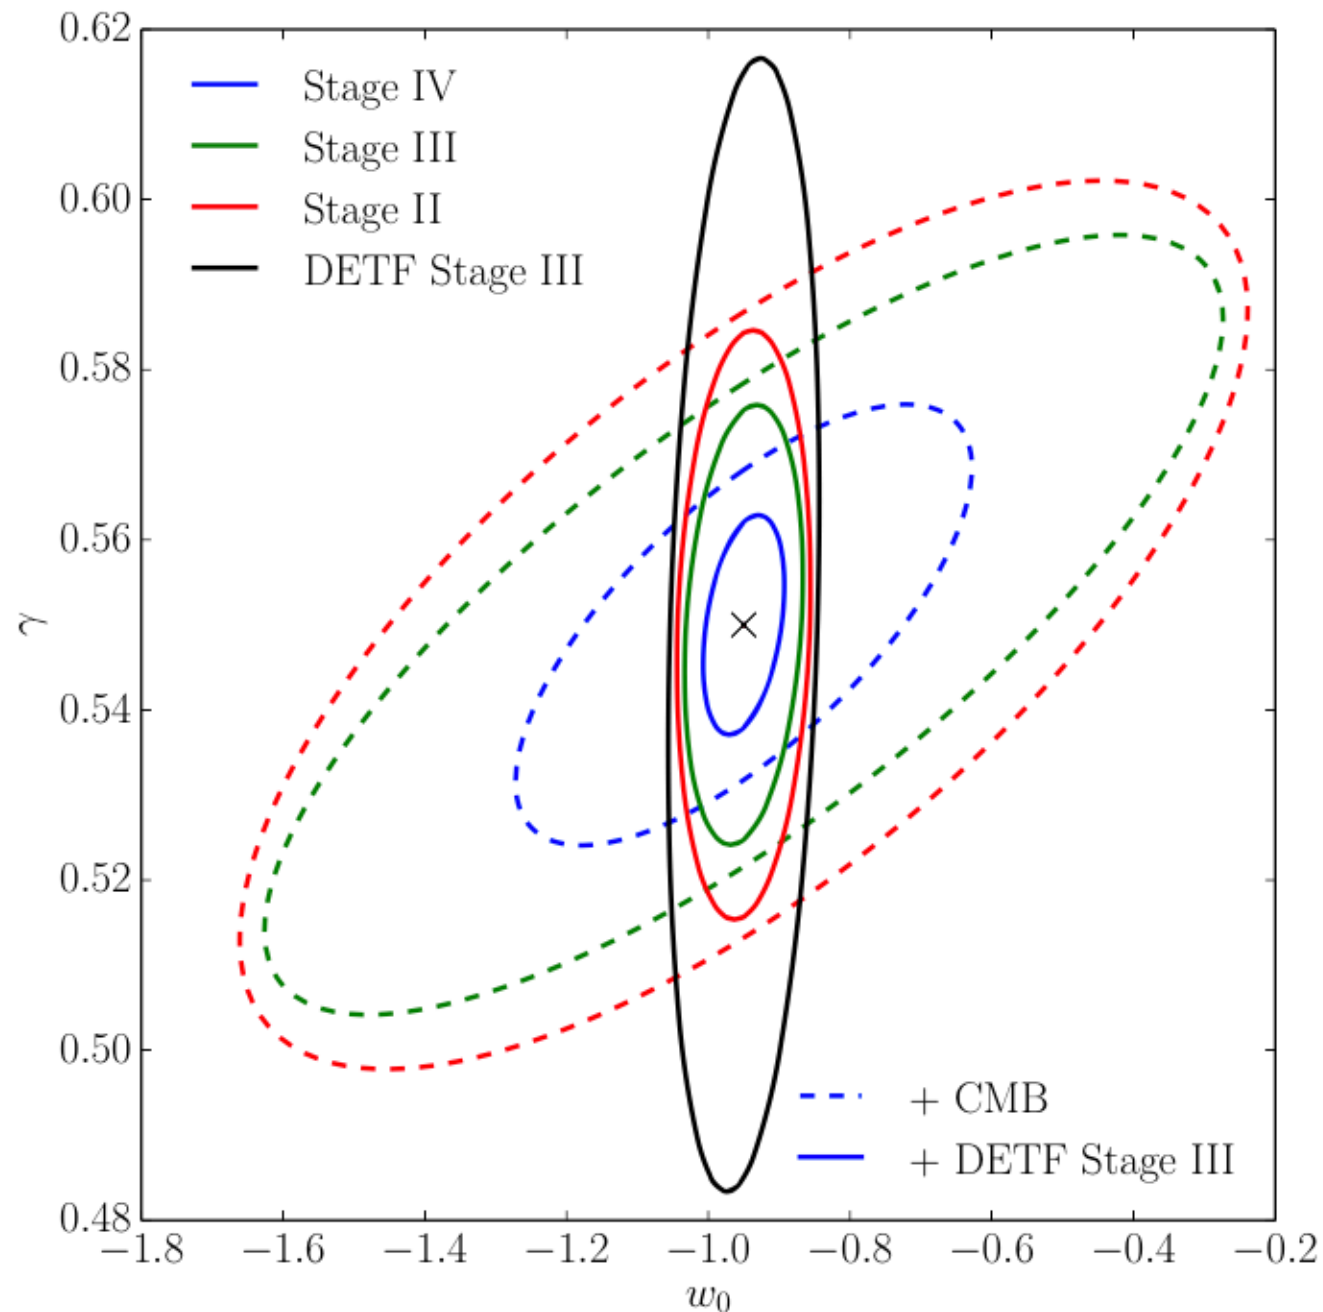

Mueller et al. (2014), arXiv: 1408.6248

Mueller et al. (2014), arXiv: 1412.0592

Summary

- **Remarkable progress in SZ cluster surveys!**
 - Over 1300 SZ identified clusters in less than 6 years
 - Unique massive, high-redshift systems that probe a new epoch of cluster formation
- **Multi-wavelength data critical to study cluster evolution and cosmology by leveraging the strengths of different data sets**
- **SZ surveys are just beginning!**
 - Future CMB polarization measurements will increase SZ-cluster samples by orders of magnitude, and enable new physics (e.g., CMB lensing, peculiar velocities, etc.)

Joint DES, SPT Cosmology: *kSZ Pairwise*

- kSZ potentially powerful probe to break degeneracy between dark energy (“ w ”) and growth (“ γ ”) constraints
- Interesting constraints on the sum of the neutrino masses
 - *A Stage IV CMB experiment kSZ constrains $\sigma(\Sigma m_\nu) \sim 30$ meV, comparable to LSST, DESI surveys*

ACT-CL/SPT-CL J0102-4915: “El-Gordo”

“*Rarest*” cluster in universe; only ~ 1 expected in universe above its mass and redshift of $M_{200} \sim 3 \times 10^{15} M_{\text{sun}}/h_{70}$ at $z=0.87$

SPT-CL J2344-4243: The “Phoenix Cluster”

- Most X-ray luminous cluster known in the Universe
- Largest star formation rate observed in a cluster BCG: $\sim 800 M_{\text{sun}} / \text{year}$
- Star formation efficiency of $\sim 30\%$; “classical” X-ray cooling rate of $2850 M_{\text{sun}} / \text{year}$

Galaxy cluster's 'starburst' surprises astronomers

Astronomers have seen a huge galaxy cluster doing what until now was only theorised to happen: making new stars.

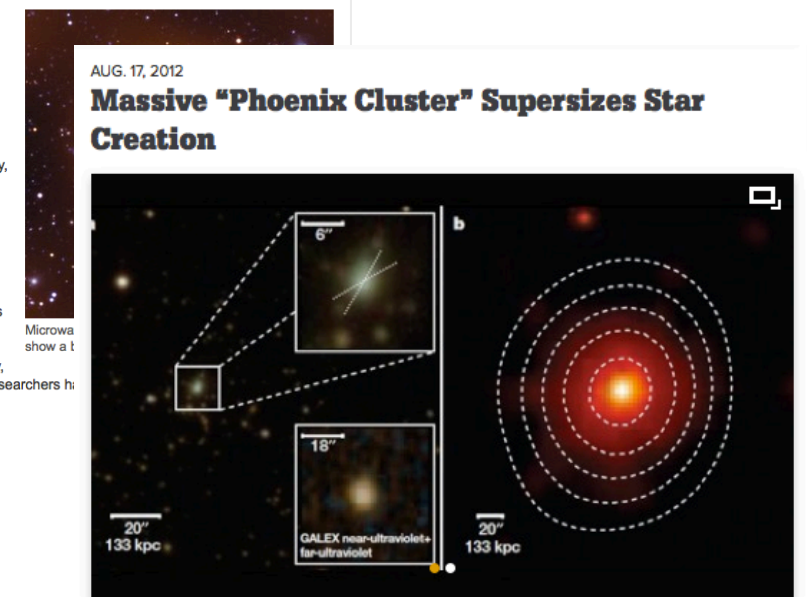

Most galaxy clusters - the largest structures in the Universe - are “red and dead”, having long since produced all the stars they can make.

But cluster formation should, according to theory, include a cooling phase, resulting in blue light from new stars.

Writing in *Nature*, researchers say they have seen evidence that the enormous Phoenix cluster makes 740 stars a year.

In our own Milky Way, only one or two new stars are made each year.

The cluster, some seven billion light-years away, is formally called SPT-CLJ2344-4243 but the researchers hope for the constellation in which it lies.

McDonald et al. (2012, 2013)

False-colour images of the galaxies and intracluster plasma in the galaxy cluster SPT-CLJ2344-4243. Figure 1 of “A massive, cooling-flow-induced starburst in the core of a luminous cluster of galaxies” published in *Nature* Vol 488, 349-352 (August 16, 2012).

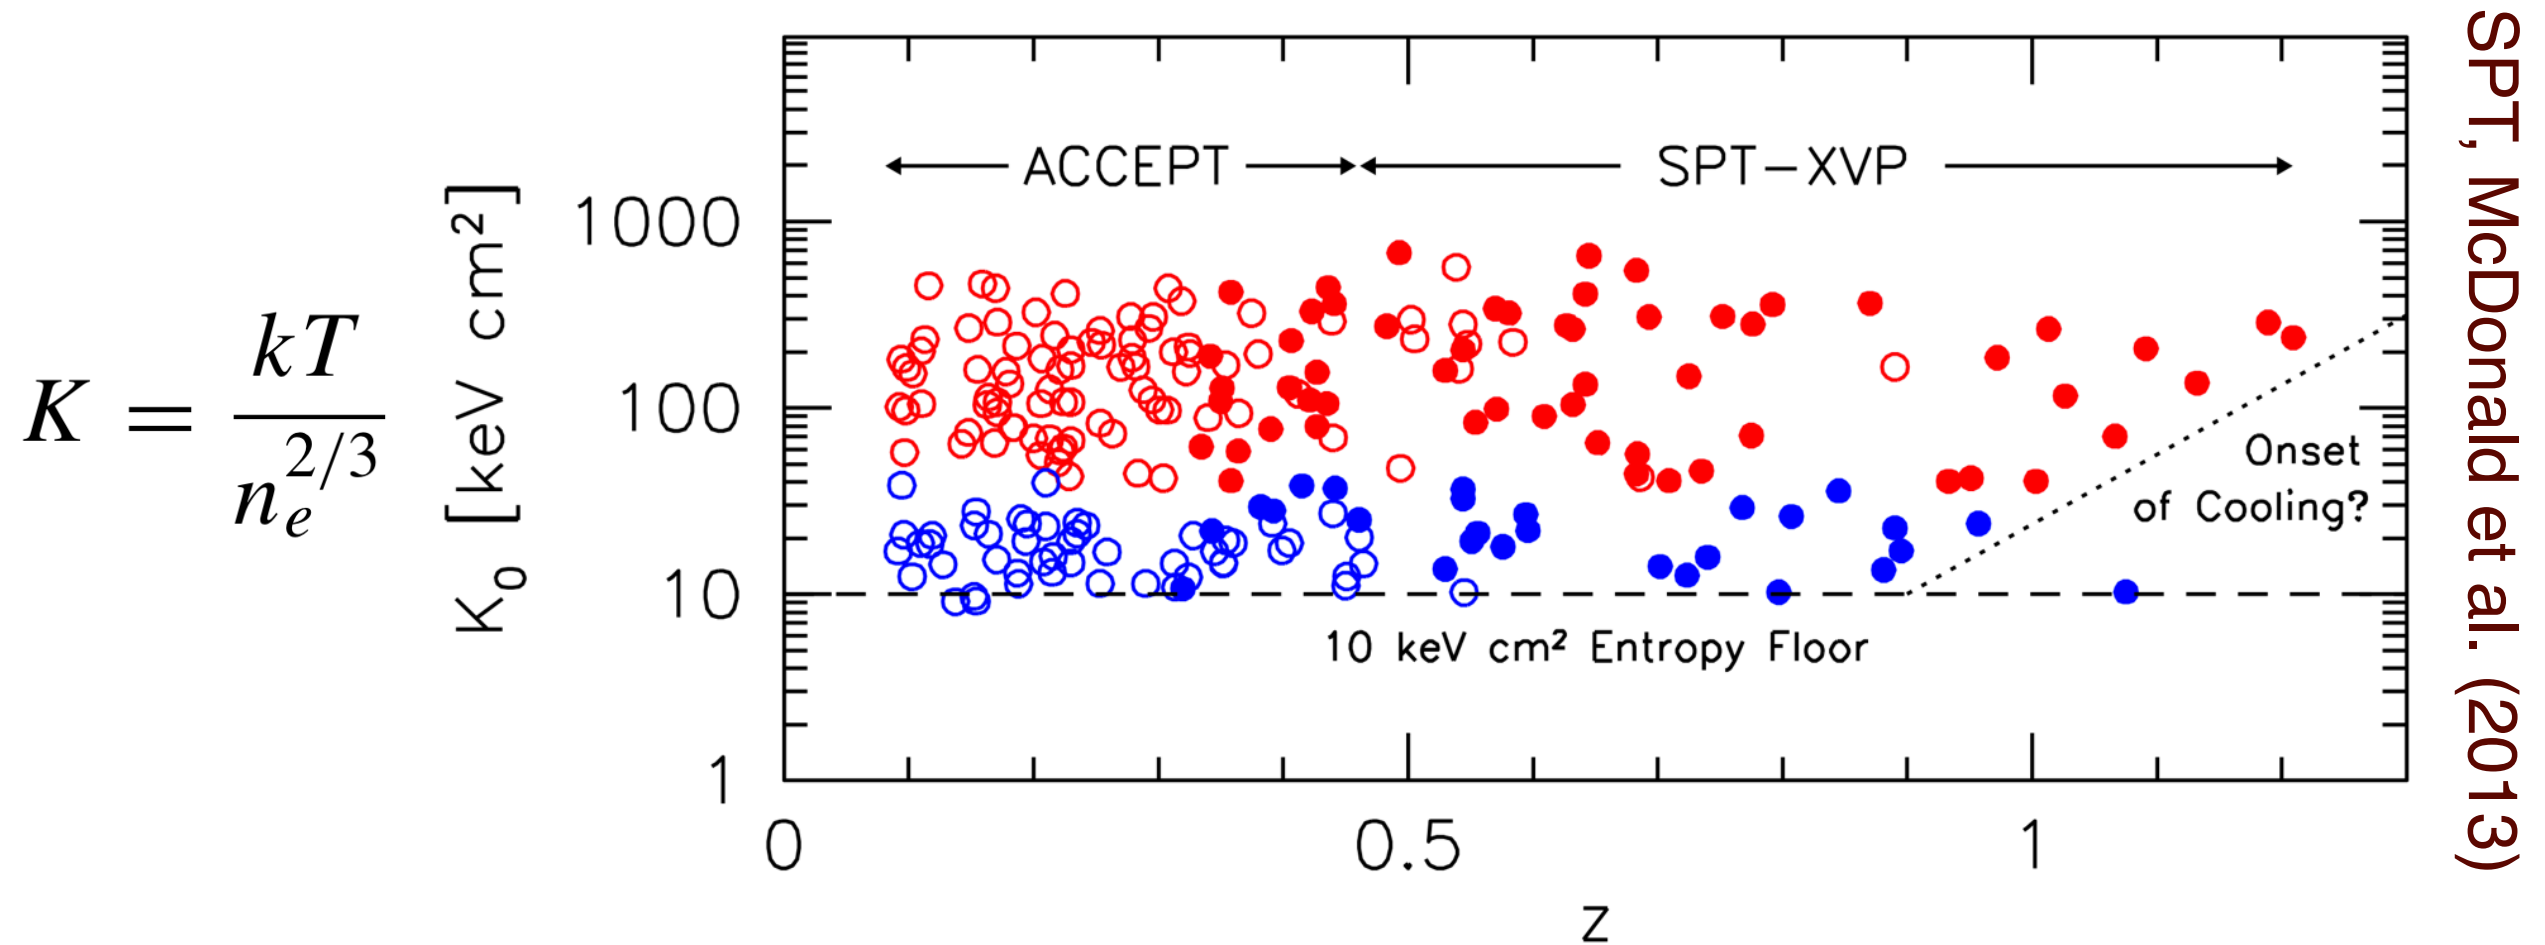

Chandra SPT-XVP (80 clusters at $z > 0.4$): Central Entropy and Cool Core Evolution

SPT, McDonald et al. (2013)

- While cluster density profiles were found to be less “peaky” at high-redshift ($z > 0.6$), i.e, no “classical” cool cores
- **There was a persistent floor in the central entropy; whatever mechanism that injects energy / entropy in clusters has been stable since $z \sim 1$**

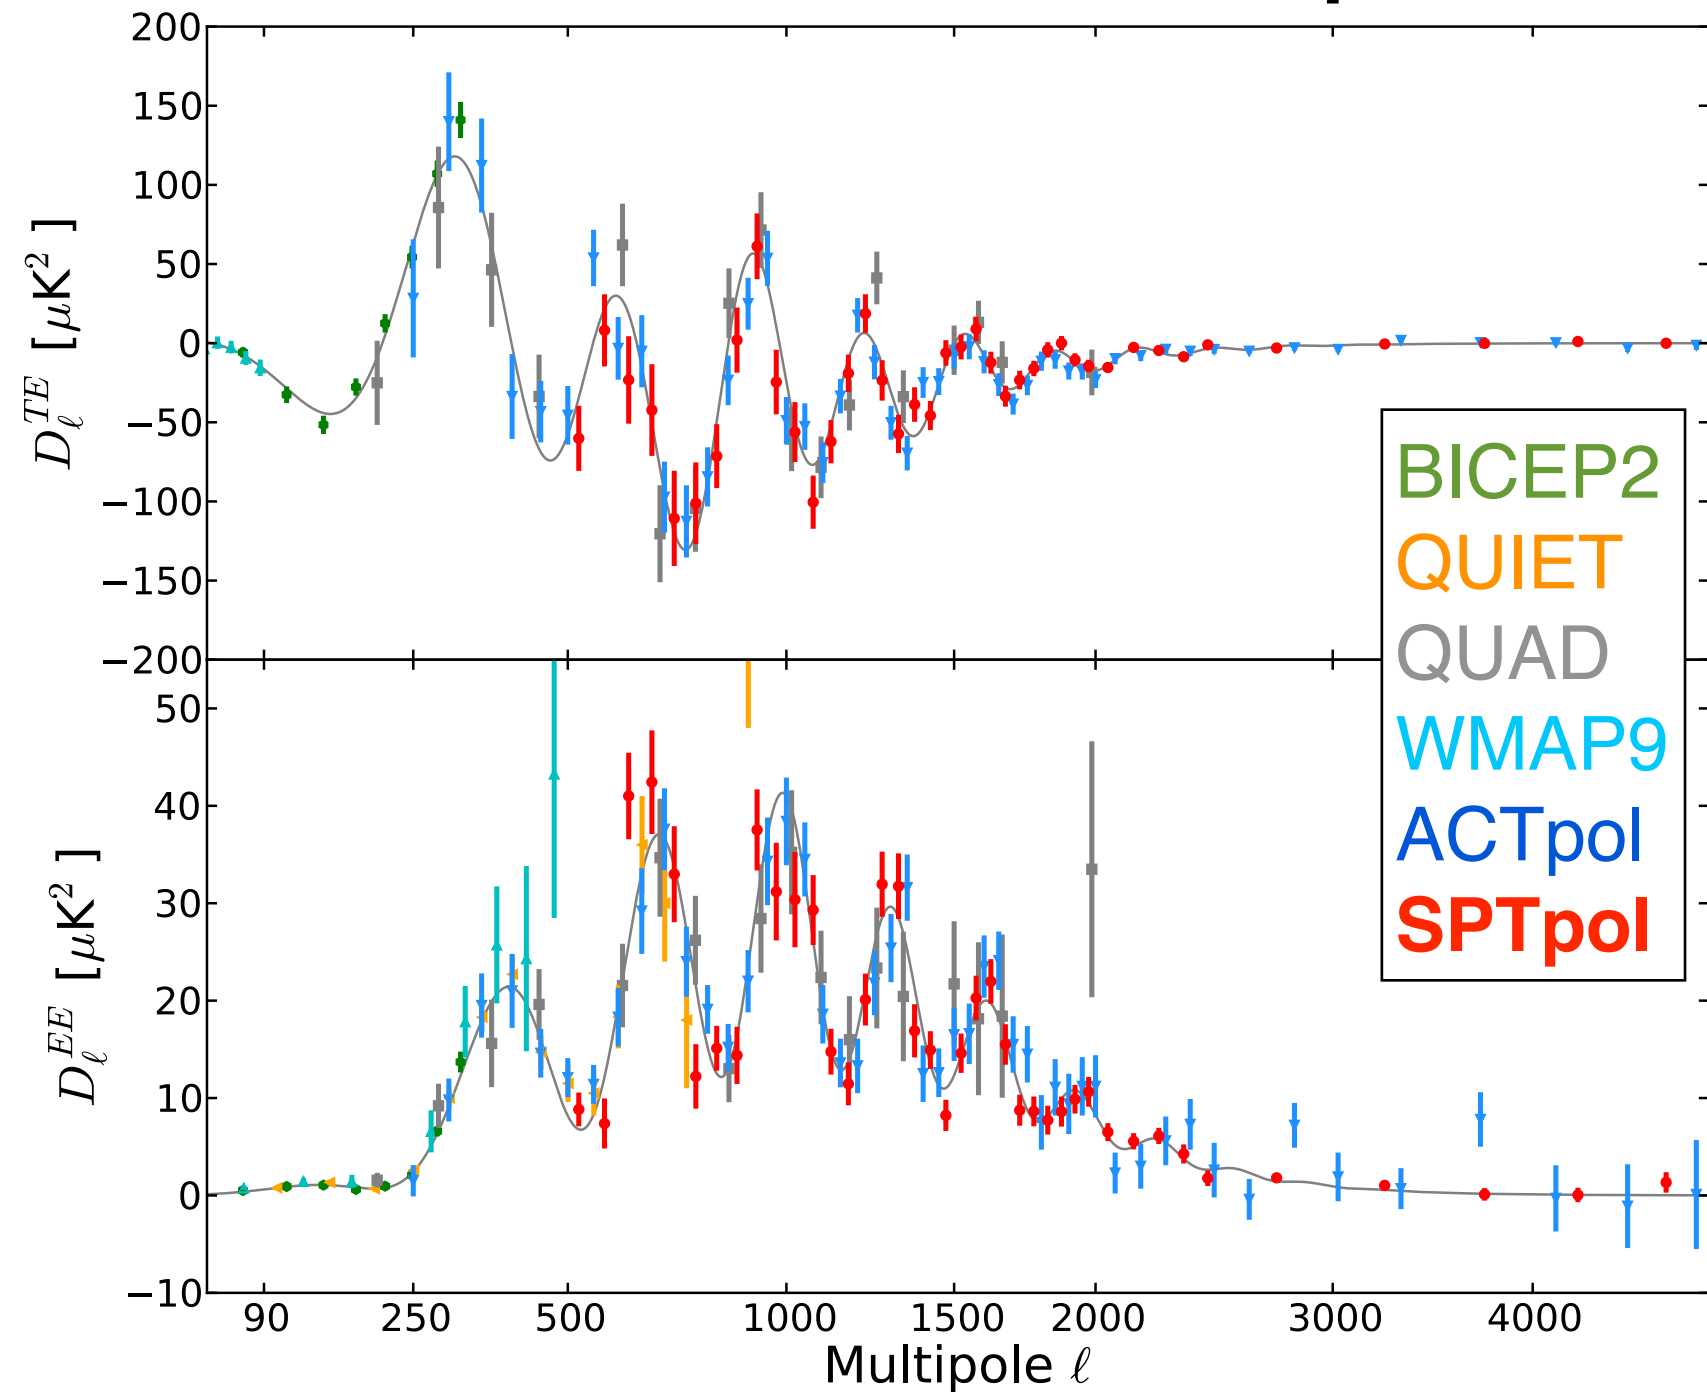

Chandra SPT-XVP (80 clusters at $z > 0.4$): Central Entropy and Cool Core Evolution

- While cluster density profiles were found to be less “peaky” at high-redshift ($z > 0.6$), i.e, no “classical” cool cores
- **There was a persistent floor in the central entropy; whatever mechanism that injects energy / entropy in clusters has been stable since $z \sim 1$**

The SPTpol Survey (2012-):

CMB Polarization Power Spectrum

- **SPTpol, 3 years of observations already!**
 - First detection of “B”-modes (Hanson et al. 2013)
 - Most precise constraints at multipoles > 1000 of TE, EE polarization power spectrum (Crites et al. 2014)
- **SPTpol Cluster Survey**
 - Wedding-cake survey: shallow (1000 deg²) and deep (500 deg²) regions
 - ***Expect to find ~600 clusters, more than SPT-SZ!***

SPTpol, Hanson et al. (2013)

SPTpol, Crites et al. (2014)

ACTpol, Naess et al. (2014)

Future SPT-3G, CMB-S4 Surveys

SZ cluster counts will increase by orders of magnitude with future surveys:

SPT-SZ/pol: $N_{\text{clust}} \sim 1,000$
SPT-3G: $N_{\text{clust}} \sim 10,000$
CMB-S4: $N_{\text{clust}} \sim 100,000+$

Deep CMB data enables CMB cluster lensing as a mass calibration tool for cluster cosmology:

SPT-3G: $\sigma(M) \sim 3\%$

CMB-S4: $\sigma(M) < \sim 0.1\%$

Especially promising for cluster masses at $z > 1$
