

Lyman- α WG

Leads: David Kirkby & Mat Pieri

Participants: Michael Blomqvist, Nicolas Busca, Julien Guy, Isabelle Paris, Javier Sanchez, Debopam Som

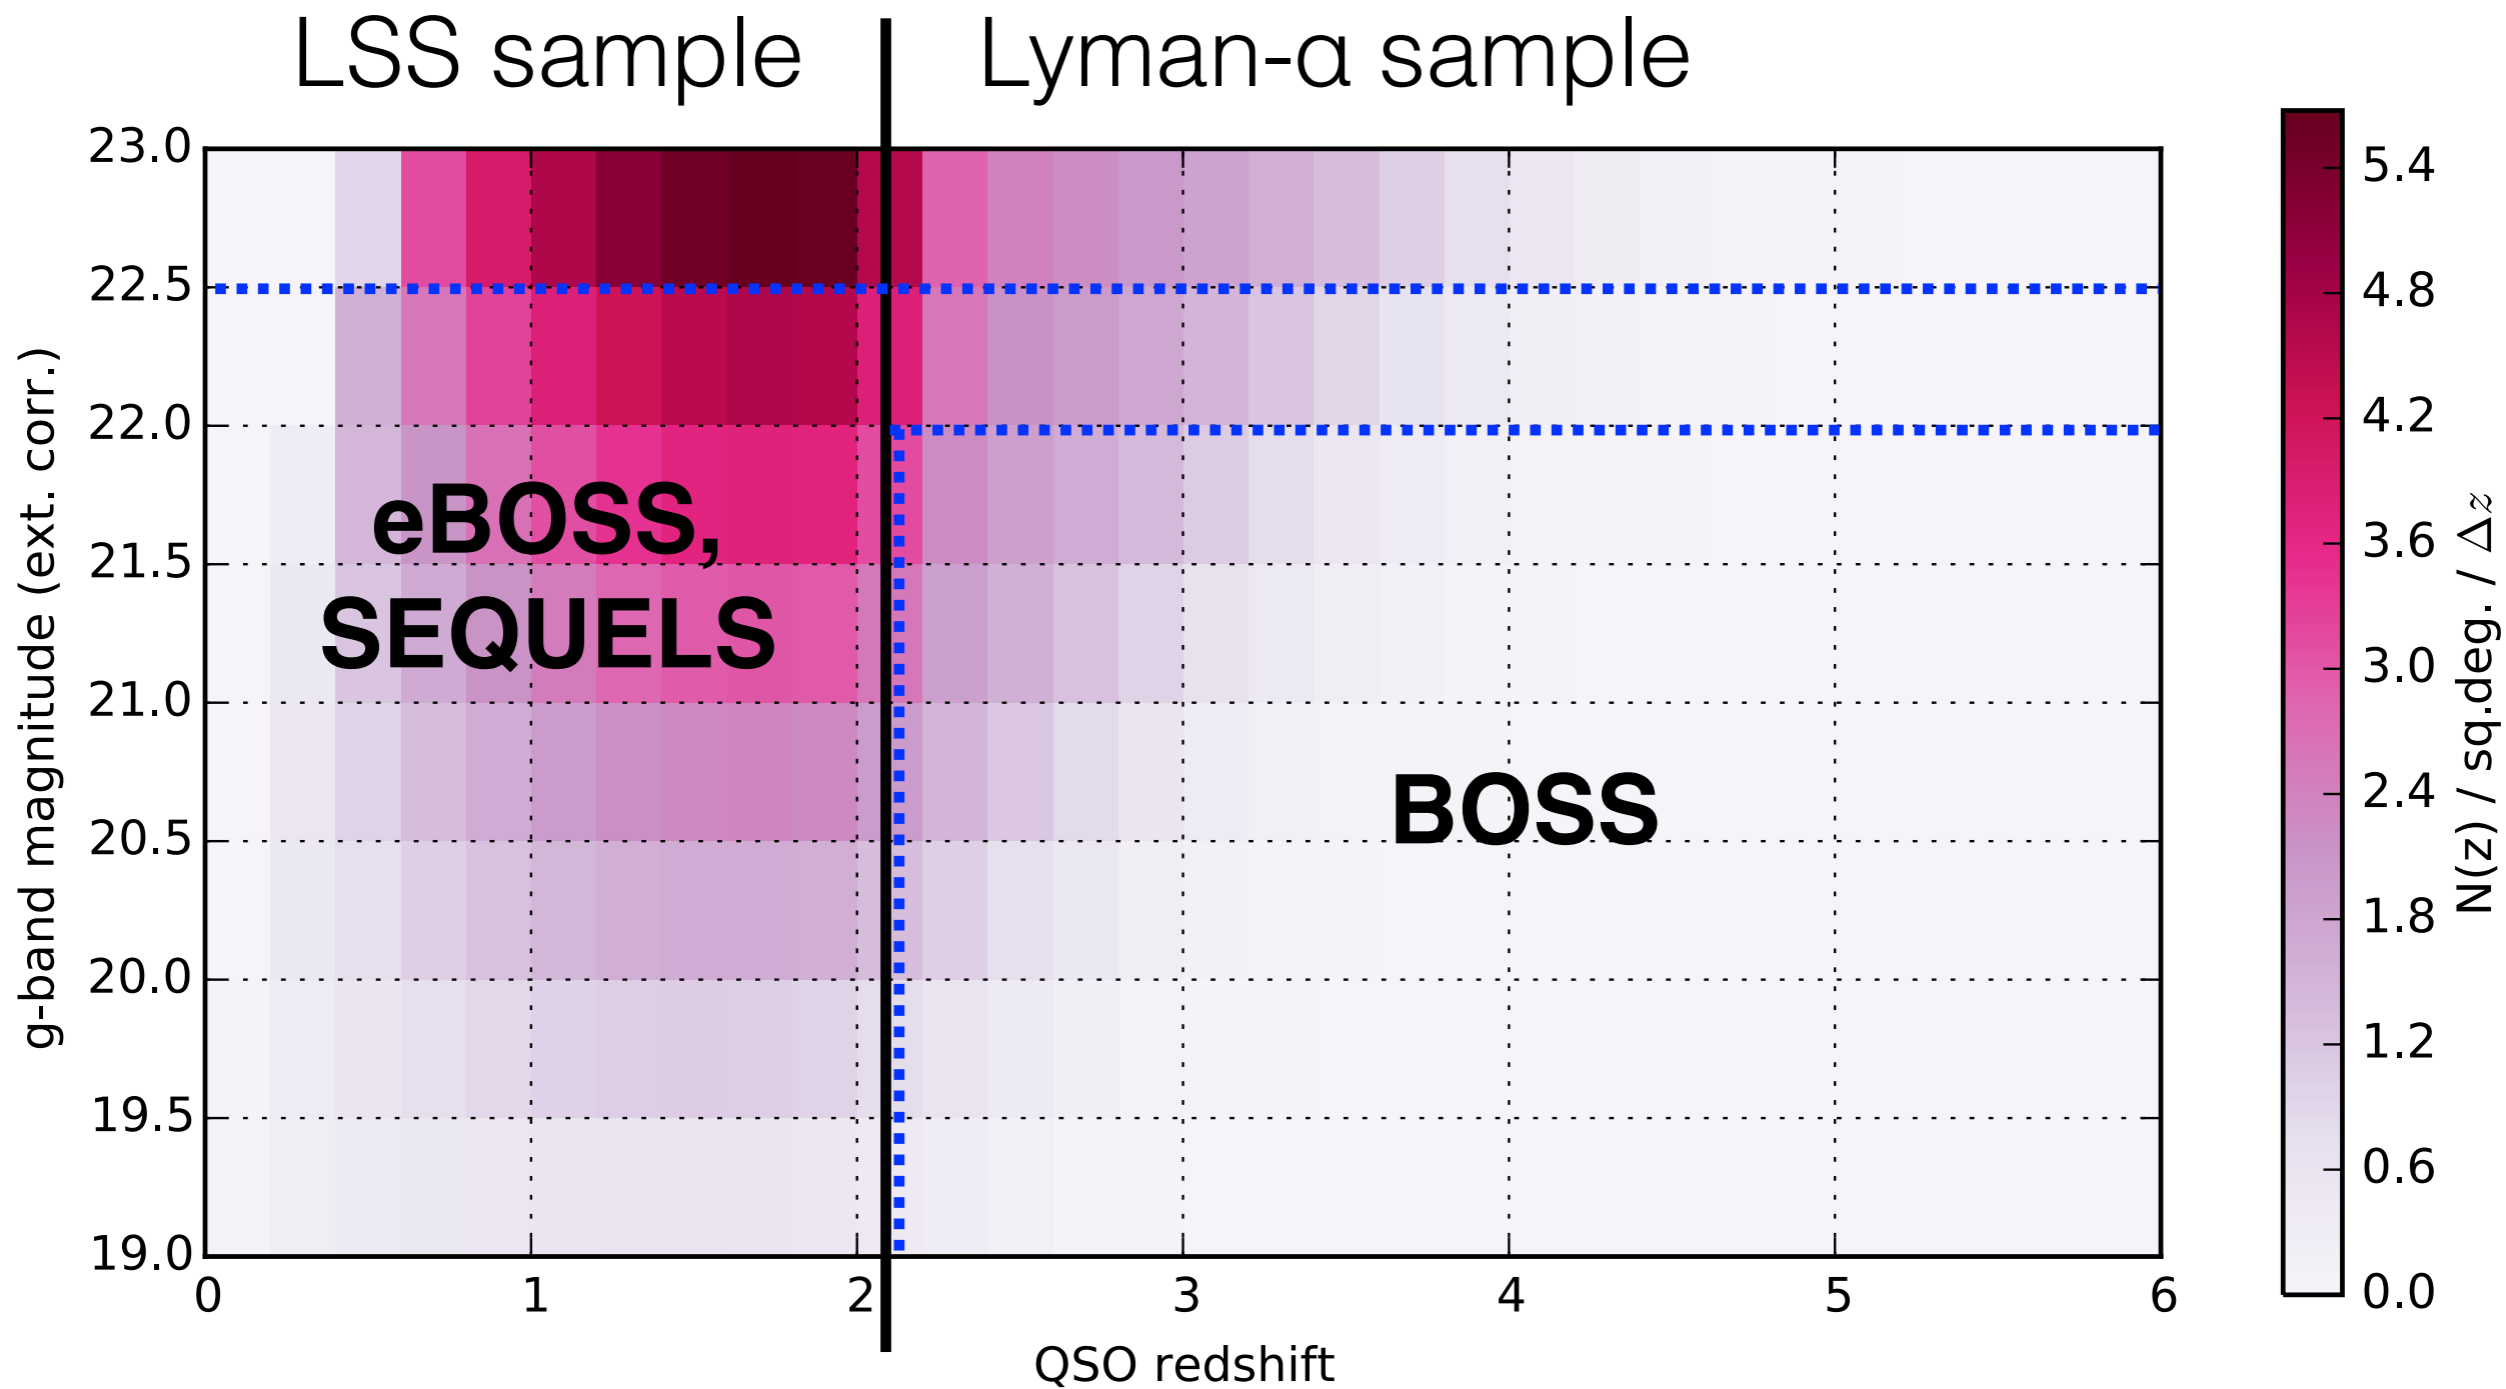

DESI Science Workshop, Argonne Nov 2015

Themes

- What can we learn from the first observation of a $g=23$ QSO target? Is it a quasar? Is it a Lyman-alpha quasar? What can we say about its redshift?
- Extend QSO templates to $g > 22$ and $z < 2.1$
- Characterize alternate hypotheses: what stars & galaxies are most likely to fake a QSO?
- Implement simple redshift chi-sq. scan.
- Investigate redmonster

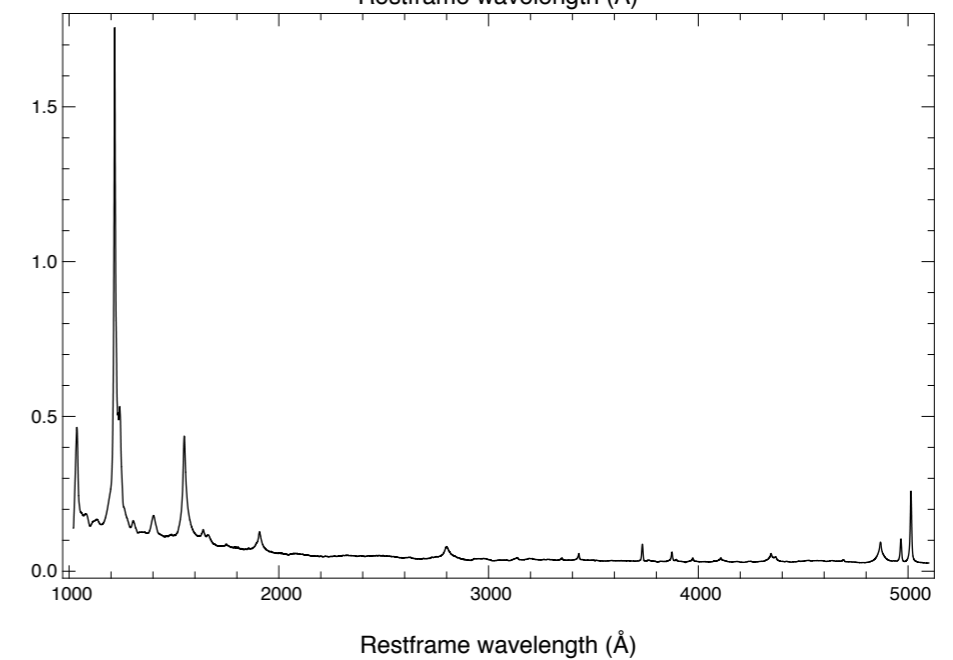

- A key targeting assumption is that only true quasars will be re-observed after the first pass (from TDR p.65):

From the first pass of targeting over the sky, we expect to identify 170 QSOs per deg² from a sample of about 260 targets per deg², for a target selection efficiency (including redshift failures) of 67%. For the subsequent passes, the target selection efficiency will be 100%, as only objects identified as $z > 2.1$ QSOs will be re-observed. After four passes, the average target selection efficiency is therefore of 88%.

Progress so far today (!)

Quantify expected QSO
diversity using PCA
analysis of DR12Q
(Isabelle Paris)

Stretch Goals

- Implement extinction corrections.
- Study impact of QSO variability:
 - How to optimally combine exposures taken ~once per year for Ly α analysis.
- Produce bricks with realistic distribution of QSOs for later study (and to test data model).

- Everyone is welcome: there is lots to do.
- Working at Argonne and Marseilles this week.
- Using github repo and issues to coordinate, share code, and document progress:
