

A 3D cutaway rendering of the CMS detector, showing its complex internal structure with various components like the calorimeters, muon chambers, and the central solenoid magnet. The rendering is semi-transparent, revealing the inner layers of the detector. The colors used are primarily red, blue, and yellow.

Future Directions for CMS Tier-3s

Ian Fisk

Tier-3s

- ▶ Tier-3s continue to be a growth area in CMS Computing
 - ▶ They now outnumber the Tier-2s (53 in SiteDB as compared to 52 Tier-2s)
 - ▶ More than half of these are in the US.
 - ▶ 12 countries have Tier-3s.

Future Directions in Tier-3s

- ▶ In CMS Tier-3s cover a diverse set of resources
 - ▶ Big variations in the amount of processing and storage
 - ▶ Dedicated facilities to fractions of share installations
- ▶ A common element is the lack of a lots of effort dedicated to CMS activities
 - ▶ Typically Tier-3s are operated by fractions of physicist time or effort from a central IT organization
- ▶ A number of the items we're looking at are intended to reduce the effort needed to operate a Tier-3

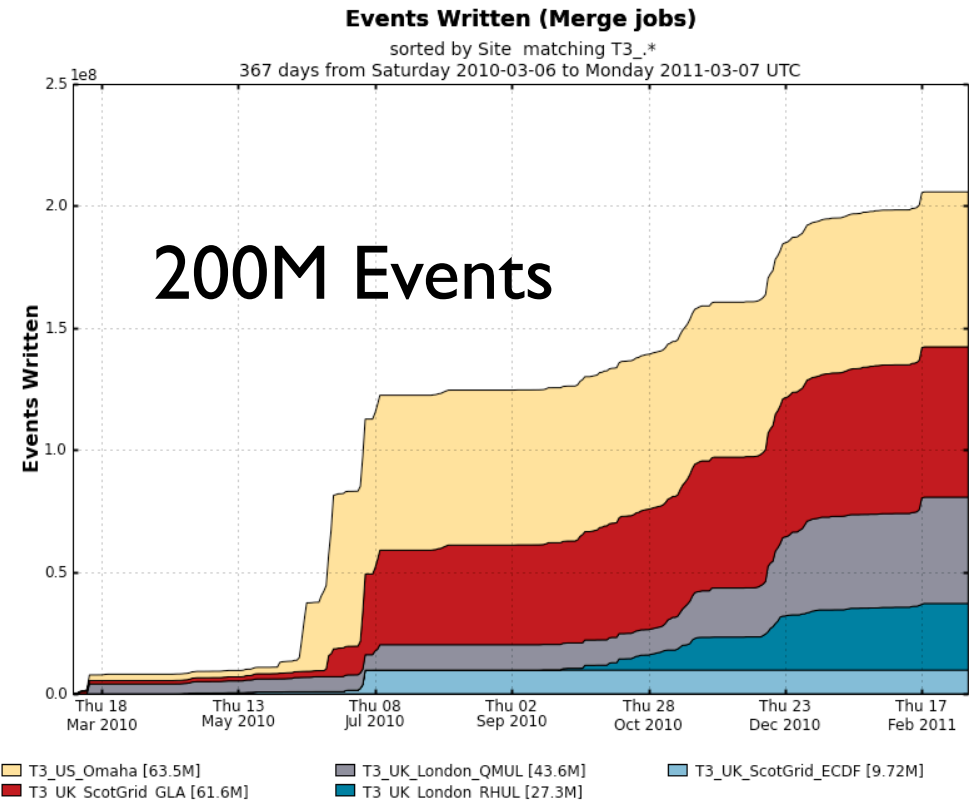

How Tier-3s Benefit CMS

- ▶ In many ways CMS has been treating Tier-3s like lower capacity Tier-2s
 - ▶ All the functionality of a Tier-2 was possible, but a full set of services was need (Grid interfaces, PhEDEx, CMS Environment, /store/user)
- ▶ When looking at simplifying we need to assess what sites gain and what CMS might potentially lose
 - ▶ CMS gains by having analysis resources operated at Tier-3s.
 - ▶ It's good for the science, but it also adds resources to CMS and it lowers the load on the Tier-2s
 - ▶ CMS gains by having opportunistic access to Tier-3s for simulated event production
 - ▶ Adds resources to the experiment

Contributions of Tier3s to Simulation

- ▶ In the last year, Tier-3s have produced about 200M simulated events
- ▶ This is a small fraction of the total, but it's additional resources
- ▶ We could potentially use more

Quandary

- ▶ How do we simplify the operations so that more sites are useful for analysis
 - ▶ While not overloading the rest of the infrastructure
 - ▶ And maintaining the other beneficial contributions from Tier-3s to CMS

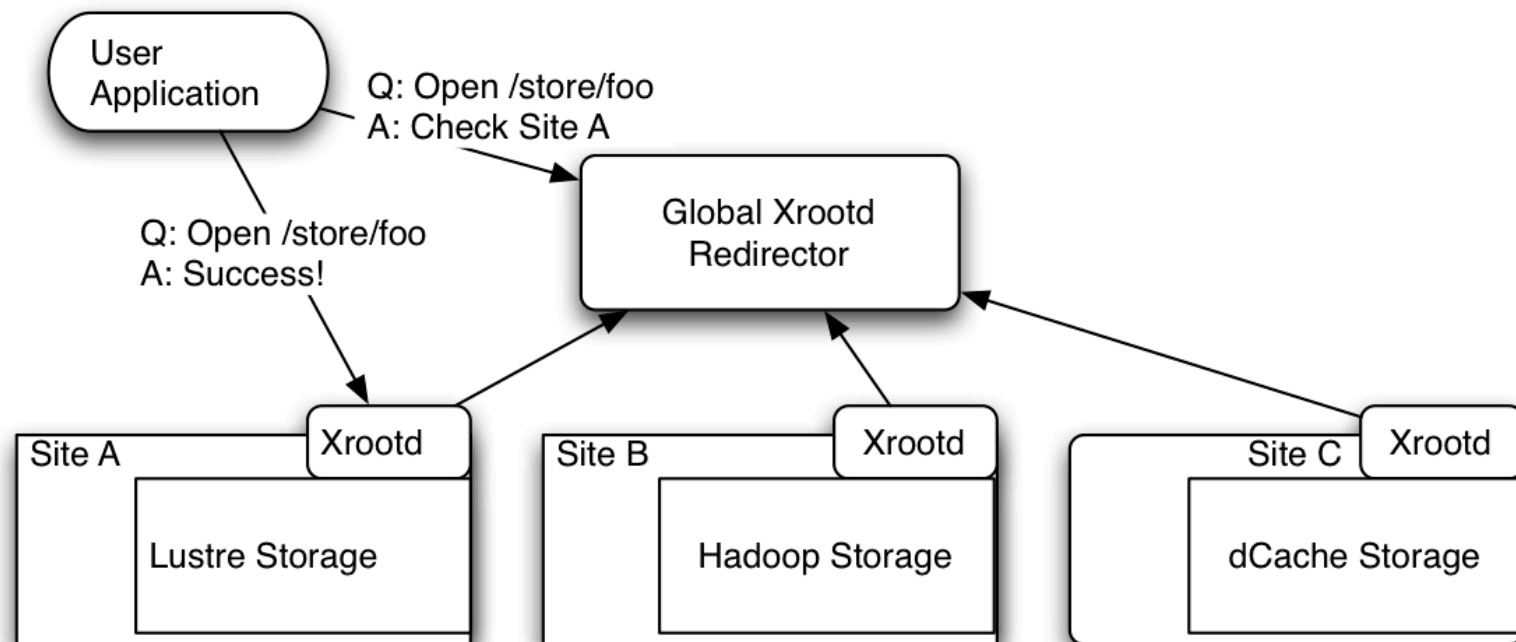

Some items in integration

- ▶ Biggest complaints we get from the Tier-3 community is the effort needed to install and operate the grid services, and the effort needed to install and operate PhEDEx
- ▶ We also get complaints about the effort needed to install and operate a cluster.
 - ▶ If you are complaining about this, please do not operate a Tier-3. It's better not to have a resource than it is to have a insecurely run center. There is enough analysis computing in centrally provided systems. Some Tier-2s with power and cooling infrastructure have been willing to host equipment in exchange for access to it.
- ▶ In response to the first 2 complaints we are investigating solutions
 - ▶ The Xrootd redirector work, should allow Tier-3s to operate diskless* (* Some limitations apply)
 - ▶ Investigating the use of CVMFS for software distribution

Diskless Tier-3s

- ▶ Instead of transferring data in advance with PhEDEx we can stream the data in with xrootd

Xrootd layers on top of existing storage element.
Think of it as a proxy (or a door) to the site's data

Benefits

- ▶ The streaming works because people have spent considerable effort trying to optimize the IO
 - ▶ Useful in particular for samples that will only be accessed once
 - ▶ Need to look more seriously at xroot local site caching
- ▶ You don't need a local PhEDEx installation or even a grid SE
- ▶ The US is a good place to test this
 - ▶ Reasonable networking
 - ▶ 2 copies of the heavily accessed AOD: a Tier-2 copy and a FNAL copy

Working

- ▶ Omaha Tier-3 is not typical
- ▶ 10Gb/s networking
- ▶ 5000 cores
- ▶ CPU efficiency looks competitive

Volume of Gigabytes Transferred By Facility
31 Days from 2010-08-01 to 2010-09-01

■ Nebraska-Xrootd-1

Maximum: 2,784 GB, Minimum: 0.04 GB, Average: 839.36 GB, Current: 10.36 GB

In use at Omaha - diskless T3!

Drawbacks

- ▶ We need to introduce some throttling on the source sites to make sure the reading centers can't knock something over
- ▶ We have estimated the impact caused by modest sized Tier-3s
 - ▶ Need to watch the relative fraction of analysis computing at Tier-3s and the level of activity
- ▶ A diskless Tier-3 is potentially operating with a storage element
 - ▶ This is fine, but need to think about what to do with user created data

Software Distribution

- ▶ CMS is currently looking at CVMFS to distribute software packages
 - ▶ CERN Virtual Machine File System is a read-only software distribution built around squid and fuse. It's used for distributing software and environments to CERN virtual machines, but it can also be used in regular machines
 - ▶ Appears to be a scalable way to have a distributed read-only file system
 - ▶ Still in the testing phase, but FNAL currently has replaced one of the read-only NFS nodes with CVMFS

Benefits

- ▶ We currently install software for sites that want it though the CE
 - ▶ This would allow sites to have the software independently of a functional CE
 - ▶ (Installing the CMS Software is not a big deal even manually)

Drawbacks

- ▶ The CVMFS system is still in integration, but is expected in production soon
- ▶ The lack of a CE would spare the site some operations but has 2 significant drawbacks
 - ▶ Local analysis users will need to run specialized versions of CRAB (supported by the sites)
 - ▶ CMS will not be able to access the site for opportunistic access

Future Directions for Tier-3s

- ▶ The goal for CMS is to make the Tier-3s efficient analysis resources
 - ▶ We are trying to respond to operations issues as they have come up
- ▶ CMS continues to benefit from sites being part of OSG
 - ▶ I think the sites also benefit because the services developed for the Tier-2s are more easily used
- ▶ There are some interesting tasks in development that may increase the utility of the Tier-3s
 - ▶ Hoping to also maintain the opportunistic access.
