

# Tracking in ILCroot with different nozzles

Muon Collider Physics  
And  
Detector Working Group

Anna Mazzacane  
Fermilab

A decorative graphic in the bottom-left corner consisting of three curved lines, each with a small blue dot at its end, curving upwards and to the right.

# Outline

- Tracking systems for MuX studies
- Nozzles geometries
- Digitization and reconstruction algorithms
- Performance studies: reconstruction efficiency and resolution
- Conclusions

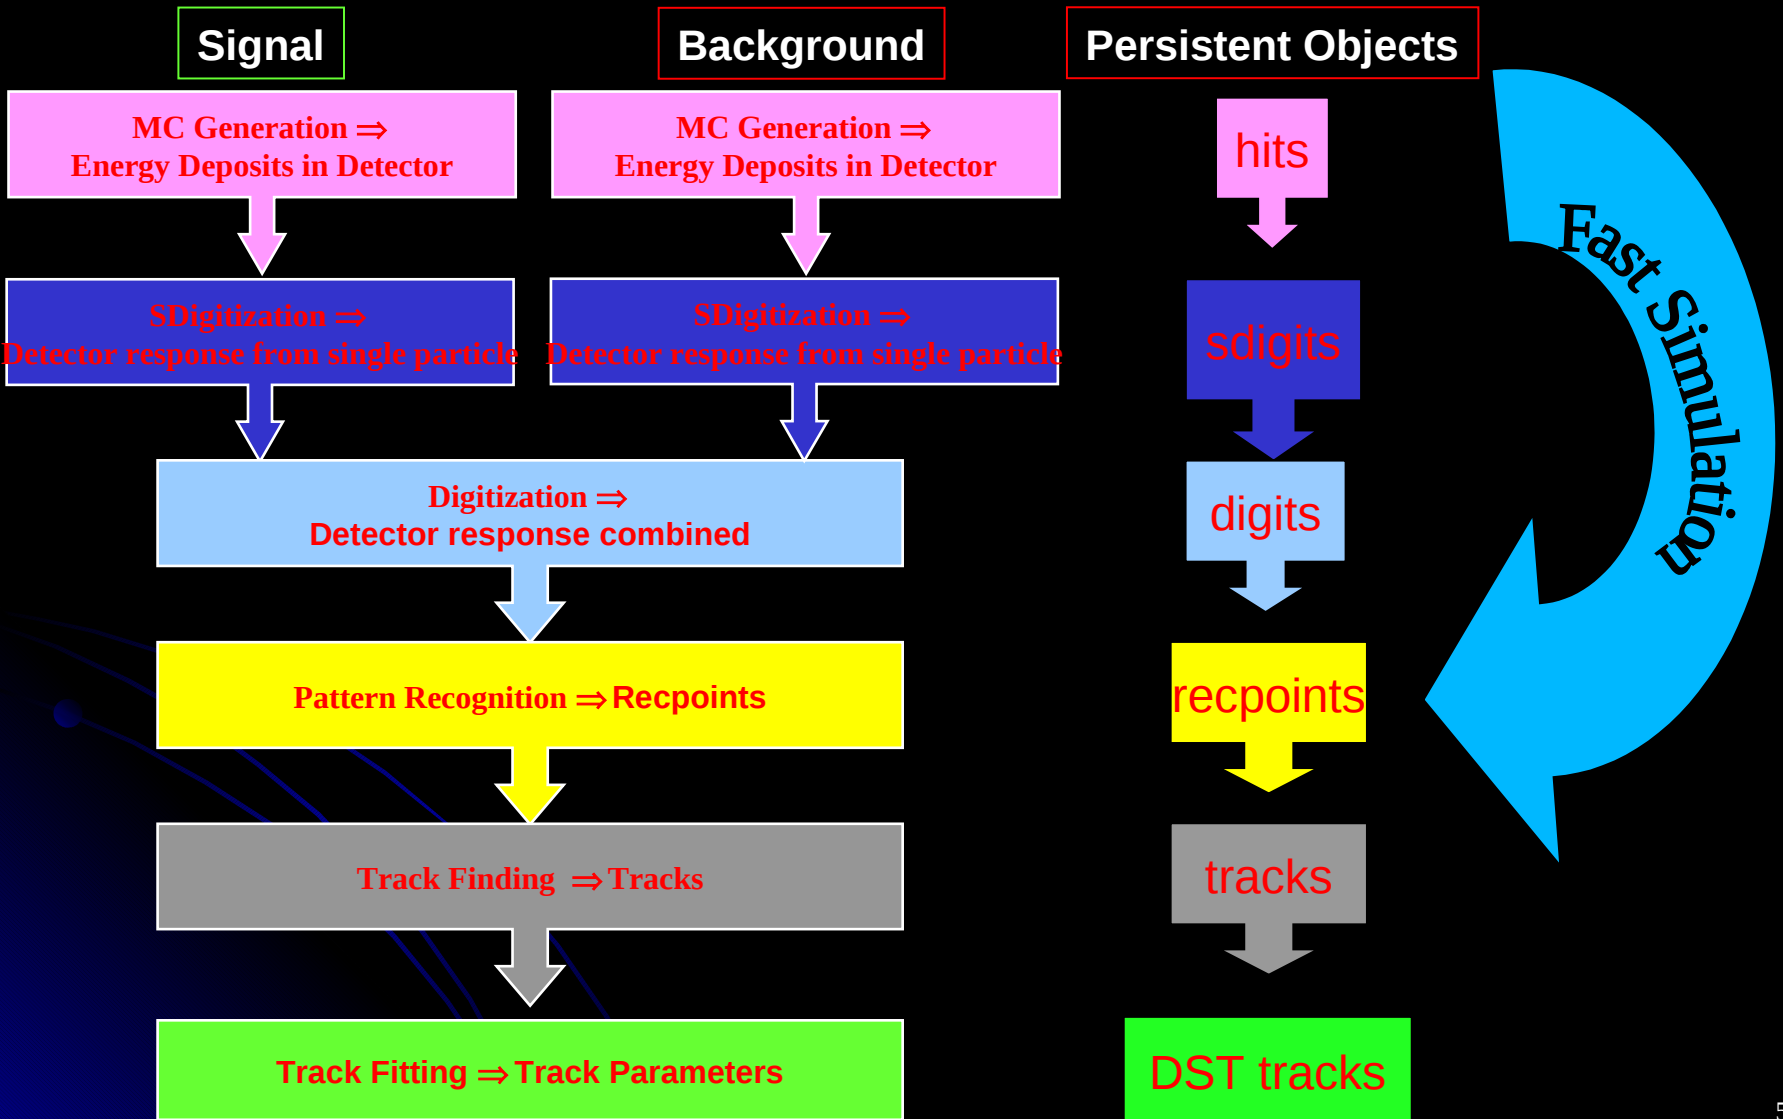

# Rationale

- Large background is expected in the tracking detectors at a MuX experiment
  - Pepper-like bkg (mostly from photons)
  - Real tracks through the detector: (beware of muons from outside)
- What matters is **NOT** the total amount of background but, rather, the ability to reconstruct tracks in a dense environment of spurious hits
- Two strategies have been implemented in ILCroot:
  - Detector layout with extra redundancy in forward region (7 disks)
  - Full parallel Kalman Filter
- Both have been implemented in ILCroot for CLIC-related studies

# ILCroot: root Infrastructure for Large Colliders

- **Software architecture based on root, VMC & Aliroot**
  - All ROOT tools are available (I/O, graphics, PROOF, data structure, etc)
  - Extremely large community of users/developers
- **Re-alignment with latest Aliroot version every 1-2 years (v4.17 release)**
- **It is a simulation framework and an Offline Systems:**
  - **Single framework, from generation to reconstruction through simulation. Don't forget analysis!!!**
  - It is immediately usable for test beams
  - Six MDC have proven robustness, reliability and portability
- **Main add-ons Aliroot:**
  - Interface to external files in various format (STDHEP, text, etc.)
  - Standalone VTX track fitter
  - Pattern recognition from VTX (for si central trackers)
  - Parametric beam background (# integrated bunch crossing chosen at run time)
- Growing number of experiments have adopted it: Alice (LHC), Opera (LNGS), (Meg), CMB (GSI), Panda(GSI), 4th Concept, (SiLC ?) and **LHeC**
- **It is Publicly available at FNAL on ILCSIM since 2006**
- **Used for ILC, CLIC and Muon Collider studies**

# Simulation steps in ILCroot: Tracking system

# Fast simulation and/or fast digitization also available in ILCroot for tracking system

- Fast Simulation = hit smearing
- Fast Digitization = full digitization with fast algorithms
- Do we need fast simulation in tracking studies?

Yes!

- Calorimetry related studies do not need full simulation/digitization for tracking
- Faster computation for quick answer to response of several detector layouts/shielding

- Do we need full simulation in tracking studies?

Yes!

- Fancy detector and reconstruction needed to be able to separate hits from signal and background

**Version** SiD01-Polyhedra + SiD01  
Guard ring: mm 0.07  
Barrel Layers: 5  
Total Tiles Barrel 7312

**Wafer layout**  
Si wafer 300 mm  
Carbonfiber in 0.228 mm  
Rohacell tickness 3.175 mm  
Carbonfiber out 0.228 mm  
Si support 300 mm x 6.667 mm x 63.8 mm  
Kapton Layer 0.1 mm

**Support layout**  
Carbon Fiber 500 mm  
Rohacell 8.075 mm  
Carbon Fiber 500 mm

# Silicon Tracker (SiT) and Forward Tracker Detector (FTD)

- 50  $\mu\text{m}$  x 50  $\mu\text{m}$  Si pixel (or Si strips or double Si strips available)
- Barrel : 5 layers subdivided in staggered ladders
- Endcap : (4+2) + (4+2) disks Si pixel
- FTD: 3 + 3 disks Si pixel

- Mostly SiD layout + FTD
- Not parametrized geometry yet

# Vertex Detector (VXD) Nozzle and Beam Pipe

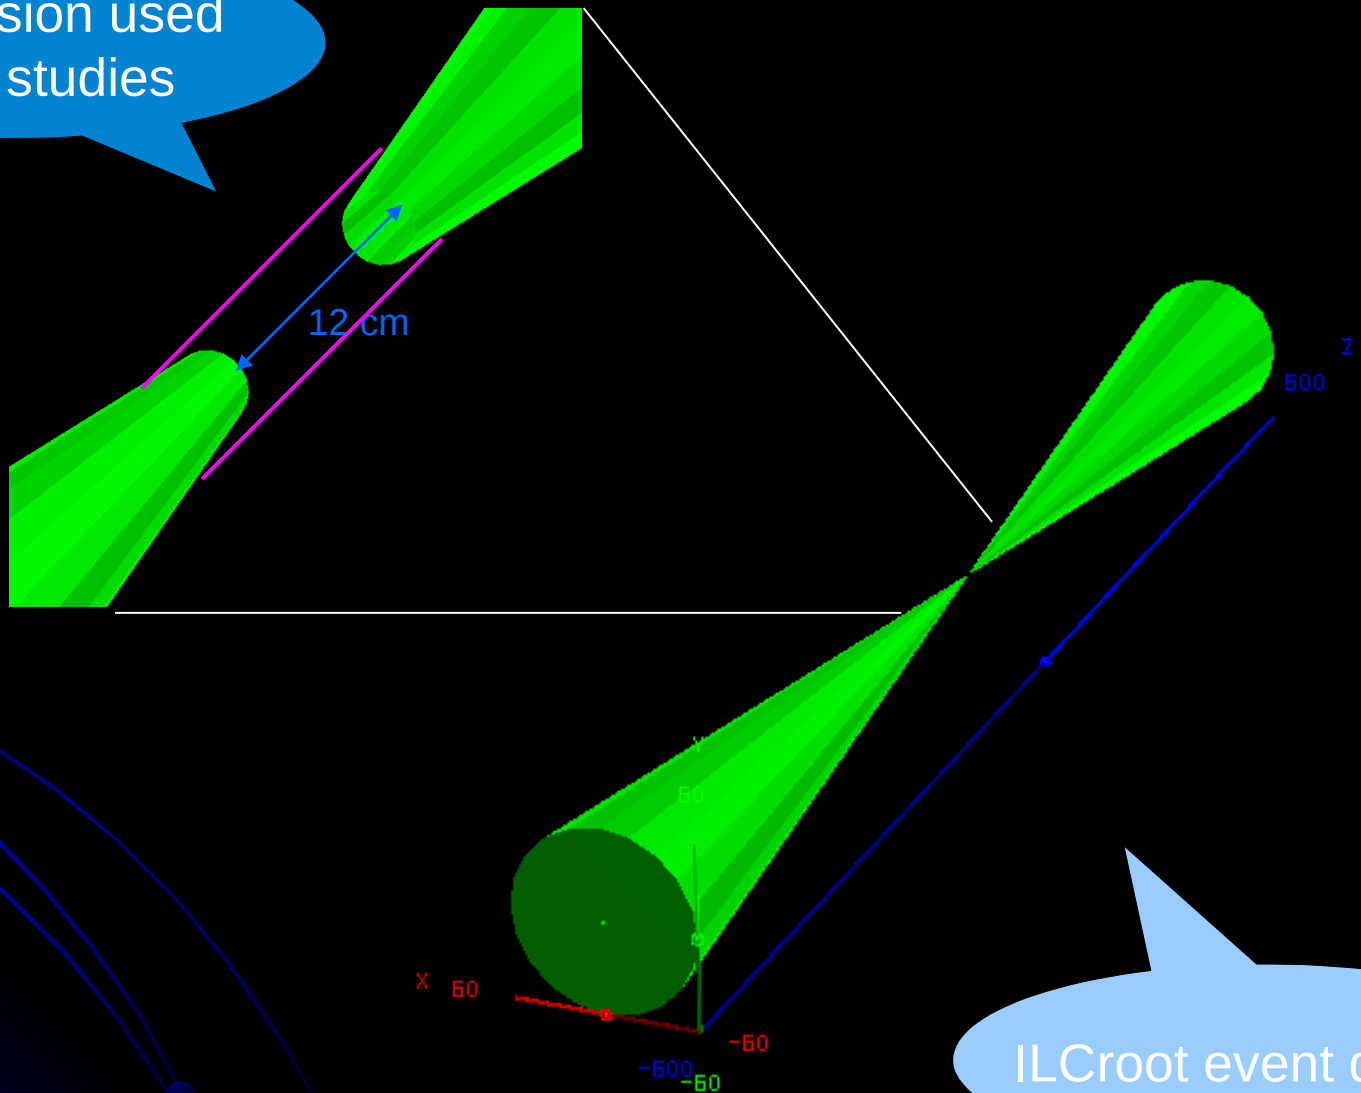

- 20  $\mu\text{m}$  x 20  $\mu\text{m}$  Si pixel
- Barrel : 5 layers subdivided in 12- 30 ladders
- Endcap : 4 + 4 disks subdivided in 12 ladders

- Mostly SiD layout
- Different dimensions (different B field = 3.5 T)
- Full parametrized geometry

# Digitization and Clusterization of Si Detectors in Ilcroot: a description of the algorithms available for detailed tracking simulation and studies

# Technologies Implemented

- 3 detector species:
  - Silicon pixels
  - Silicon Strips
  - Silicon Drift
- Pixel can have non constant size in different layers
- Strips can also be stereo and on both sides
- Dead regions are taken into account
- Algorithms are parametric: almost all available technologies are easily accomodated (MAPS, 3D, DEPFET, etc.)

Used for VXD SiT and  
FTD  
in present studies

# SDigitization in Pixel Detector (production of summable digits)

- Summable digit = signal produced by each individual track in a pixel
- Loop over the hits produced in the layer and create a segment in Si in 3D
  - Step (from MC) along the line  $>1 \mu\text{m}$  increments
    - Convert GeV to charge and get bias voltage:  
 $q = dE*dt/3.6e-9$      $dV = \text{thick}/\text{bias voltage}$
    - Compute charge spreading:  
 $\sigma_{xy} = \text{sqrt}(2k/e*T^{\circ}*dV*L)$ ,     $\sigma_z = fda*\sigma_{xy}$
    - Spread charge across pixels using  $\text{Erfc}(xy,z,\sigma_{xy},\sigma_z)$
  - Charge pile-up is automatically taken into account

# SDigitization in Pixels (2)

- Add couplig effect between nearby pixels row-wise and column-wise (constant probability)
- Remove dead pixels (use signal map)

# Digitization in Pixels

Digit = sum of all sdigit corresponding to the same pixel

- Load SDigits from several files (signal or multiple background)
- Merge signals belonging to the same pixel
  - Non-linearity effects
  - Saturation
- Add electronic noise
- Save Digits over threshold

# Clusterization in Pixel Detector

Cluster = a collection of nearby digit

Create a initial cluster from adjacent pixels (no for diagonal)

Subdivide the previous cluster in smaller  $N \times N$  clusters

Reconstruct cluster and error matrix from coordinate average of the cluster

Kalman filter picks up the best cluster

# Parameters used for the pixel tracking detectors in current MuX studies

Size Pixel X = 20  $\mu\text{m}$  (VXD and FTD), 50  $\mu\text{m}$  (SiT)

Size Pixel Z = 20  $\mu\text{m}$  (VXD and FTD), 50  $\mu\text{m}$  (SiT)

Eccentricity = 0.85 (fda)

Bias voltage = 18 V

cr = 0% (coupling probability for row)

cc = 4.7% (coupling probability for column)

threshold = 3000 electrons

electronics noise = 0 electrons

$T^\circ = 300 \text{ }^\circ\text{K}$

# Track Fitting in ILCRoot

Track finding and fitting is a global task: individual detector collaborate

It is performed after each detector has completed its local tasks (simulation, digitization, clusterization)

It occurs in three phases:

1. Seeding in SiT and fitting in VXD+SiT+MUD
2. Standalone seeding and fitting in VXD
3. Standalone seeding and fitting in MUD

Two different seedings:

- A. Primary seeding with vertex constraint
- B. Secondary seeding without vertex constraint

Not yet implemented

# Kalman Filter (classic)

- Recursive least-squares estimation.
- Equivalent to global least-squares method including all correlations between measurements due to multiple scattering.
- Suitable for combined track finding and fitting
- Provides a natural way:
  - to take into account multiple scattering, magnetic field inhomogeneity
  - possibility to take into account mean energy losses
  - to extrapolate tracks from one sub-detector to another

# Parallel Kalman Filter

- Seedings with constraint + seedings without constraint at different radii (necessary for kinks and V0) from outer to inner
- Tracking
  - Find for each track the prolongation to the next layer
  - Estimate the errors
  - Update track according current cluster parameters
  - (Possible refine clusters parameters with current track)
- Track several track-hypothesis in parallel
  - Allow cluster sharing between different track
- Remove-Overlap
- **Kinks and V0** fitted during the Kalman filtering

# Tracking Strategy – Primary Tracks

- Iterative process
  - **Seeding in SiT**
  - Forward propagation towards to the vertex  
 $\text{SiT} \rightarrow \text{VXD}$
  - **Back propagation towards to the MUD**  
 $\text{VXD} \rightarrow \text{SiT} \rightarrow \text{MUD}$
  - **Refit inward**  
 $\text{MUD} \rightarrow \text{SiT} \rightarrow \text{VXD}$
- Continuous seeding –track segment finding in all detectors

# VXD Standalone Tracking

- Uses Clusters leftover in the VXD by Parallel Kalman Filter
- **Requires at least 4 hits to build a track**
- Seeding in VXD in two steps
  - Step 1: look for 3 Clusters in a narrow row or 2 Clusters + IP constraint
  - Step 2: prolongate to next layers each helix constructed from a seed
- After finding Clusters, all different combination of clusters are refitted with the Kalman Filter and the tracks with lowest  $\chi^2$  are selected
- Finally, the process is repeated attempting to find tracks on an enlarged row constructed looping on the first point on different layers and all the subsequent layers
- In 3.5 Tesla B-field  $P_t > 20$  MeV tracks reconstructable

# Performance studies

Resolution

# Conclusions

- A full simulation and reconstruction of Si-tracking detectors is implemented in ILCroot
- Pattern recognition and Kalman Filter have been continuously improved over the past 4 years for ILC and CLIC studies (F. Ignatov)
- Preliminary studies indicate that current nose (September 2010, 10°) has slightly lower geometrical efficiency than skinned nose
  - More material in the game
  - Geant4 interference between detector and nozzle volumes in the game (see N. Terentiev talk on Nov. 10th)
- Implementation of new Si-detector compatible with 10° nozzle will start immediatly
- Assistance by F. Ignatov is of paramount importance to fine-tune track reconstrucion
- Repeat current studies with background (next talk)

# Backup slides

# SDigitization in Strips Detector

- Get the Segmentation Model for each detector (from IlcVXDSegmentationSSD class)
- Get Calibration parameters (from IlcVXDCalibrationSSD class)
- Load background hits from file (if any)
- Loop on the hits and create a segment in Si in 3D

Step along the line in equal size increments

- Compute Drift time to p-side and n-side:

```
tdrift[0] = (y+(seg->Dy()*1.0E-4)/2)/GetDriftVelocity(0);
```

```
tdrift[1] = ((seg->Dy()*1.0E-4)/2-y)/GetDriftVelocity(1);
```

- Compute diffusion constant:

```
sigma[k] = TMath::Sqrt(2*GetDiffConst(k)*tdrift[k]);
```

- integrate the diffusion gaussian from  $-3\sigma$  to  $3\sigma$

– Charge pile-up is automatically taken into account

# SDigitization in Strips (2)

- Add electronic noise per each side separately

```
// noise is gaussian
noise = (Double_t) gRandom->Gaus(0,res->GetNoiseP().At(ix));

// need to calibrate noise
noise *= (Double_t) res->GetGainP(ix);

// noise comes in ADC channels from the calibration database
// It needs to be converted back to electronVolts
noise /= res->GetDEvToADC(1.);
```

- Add coupling effect between nearby strips
  - different contribution from left and right neighbours
  - Proportional to nearby signals

- Remove dead pixels (use signal map)

- Convert total charge into signal (ADC count)

```
if(k==0) signal /= res->GetGainP(ix);
else signal /= res->GetGainN(ix);
```

```
// signal is converted in unit of ADC
```

```
signal = res->GetDEvToADC(fMapA2->GetSignal(k,ix));
```

# Clusterization in Strip Detector

- Create a initial cluster from adjacent strips (no for diagonal)
- Separate into Overlapped Clusters
  - Look for through in the analog signal shape
  - Split signal of parent clusters among daughter clusters
- Intersect stereo strips to get Recpoints from CoG of signals (and error matrix)
- Kalman filter picks up the best Clusters

# The Parameters for the Strips

- Strip size (p, n)
- Stereo angle (p-> 7.5 mrad, n->25.5 mrad)
- Ionization Energy in Si = 3.62E-09
- Hole diffusion constant (= 11 cm<sup>2</sup>/sec)
- Electron diffusion constant (= 30 cm<sup>2</sup>/sec)
- $v_{\text{drift}}^{\text{P}}$  (=0.86E+06 cm/sec) ,  $v_{\text{drift}}^{\text{N}}$  (=2.28E+06 cm/sec)
- Calibration constants
  - Gain
  - ADC conversion (1 ADC unit = 2.16 KeV)
- Coupling probabilities between strips (p and n)
- $\sigma$  of gaussian noise (p AND n)
- threshold
