Neutrino Frontier Probes of Dark Sectors

Kevin J. Kelly, Fermilab
Snowmass CPM Session 127, October 6 2020
Identify and classify the types of dark sector searches that can be studied in neutrino experiments.

I will focus on accelerator beam environments for some specificity, but there are many other ways that neutrino experiments can search for dark sectors.

<table>
<thead>
<tr>
<th>Model</th>
<th>Production</th>

Sampling of Detectors

- Experiments that can search for many of these models (often simultaneously) – **not** an exhaustive list!

CHARM | MINOS | MINERvA
----- | ----- | -----
Nu-Cal | MiniBooNE(-DM) | T2K | T2HK
MicroBooNE | ICARUS | SBND | DUNE
COHERENT | Super-Kamiokande | Borexino

For more, see the [NF03 Workshop Oct. 3rd](#)
Dedicated beam dump run of MiniBooNE: DM can be produced via the decays of neutral pions or in bremsstrahlung and travel to MiniBooNE, where they can scatter off nucleons/electrons.

- Beam dump suppresses neutrino “background” significantly, allowing for incredible sensitivity.

Subset of theoretical work that inspired this: [0906.5614], [1107.4580], [1205.3499]
Beam Dump operation occurred in 2013/2014, with a total of $1.86 \times 10^{20}$ Protons on Target.

Because of the dedicated Beam Dump operation, the limit set on light dark matter is among the most powerful, and is difficult for next-generation experiments to surpass without their own beam dump plans.
Beam Dump operation occurred in 2013/2014, with a total of $1.86 \times 10^{20}$ Protons on Target.

Because of the dedicated Beam Dump operation, the limit set on light dark matter is among the most powerful, and is difficult for next-generation experiments to surpass without their own beam dump plans.

Are there ways of suppressing neutrino backgrounds without dedicated beam dump runs?
Dark Mediator Decays in DUNE

Symbiotic – can perform highly sensitive searches during neutrino beam operation. In fact, focusing of charged mesons can enhance sensitivity to some dark sector scenarios.
Tools for Accelerator-Produced Dark Sectors

**GENIE-based code for DM production and DM/SM interactions**

Models that produce a flux of semi-relativistic or relativistic boosted dark matter at large neutrino detectors are well-motivated extensions beyond the minimal weakly interacting massive particle (WIMP) paradigm. Current and upcoming liquid argon time projection chamber (LArTPC) based detectors will have improved sensitivity to such models, but also require improved theoretical modeling to better understand their signals and optimize their analyses. I present the first full Monte Carlo tool for boosted dark matter interacting with nuclei in the energy regime accessible to LArTPC detectors, including the Deep Underground Neutrino Experiment (DUNE). The code uses the nuclear and strong physics modeling of the GENIE neutrino Monte Carlo event generator with particle physics modeling for dark matter. The code will be available in GENIE v3. In addition, I present a code for generating a GENIE-compatible flux of boosted dark matter coming from the Sun that is released independently.

Sensitive searches in large neutrino detectors

O(10) GeV Beam Dump from PIP-II (LOI Link):
Impressive coverage of thermal relic target
Conclusions

▸ Neutrino experiments combined with intense beams provide a mechanism to search for many interesting, well-motivated dark sector scenarios.

▸ Rich phenomenology between different production mechanisms (including using the neutrino beam itself), different scattering signatures, and different decay signatures.

▸ Searches can be performed in dedicated “beam dump” modes or simultaneously with neutrino beam operation – different benefits and disadvantages for each.

Stay tuned for more. Thanks!
