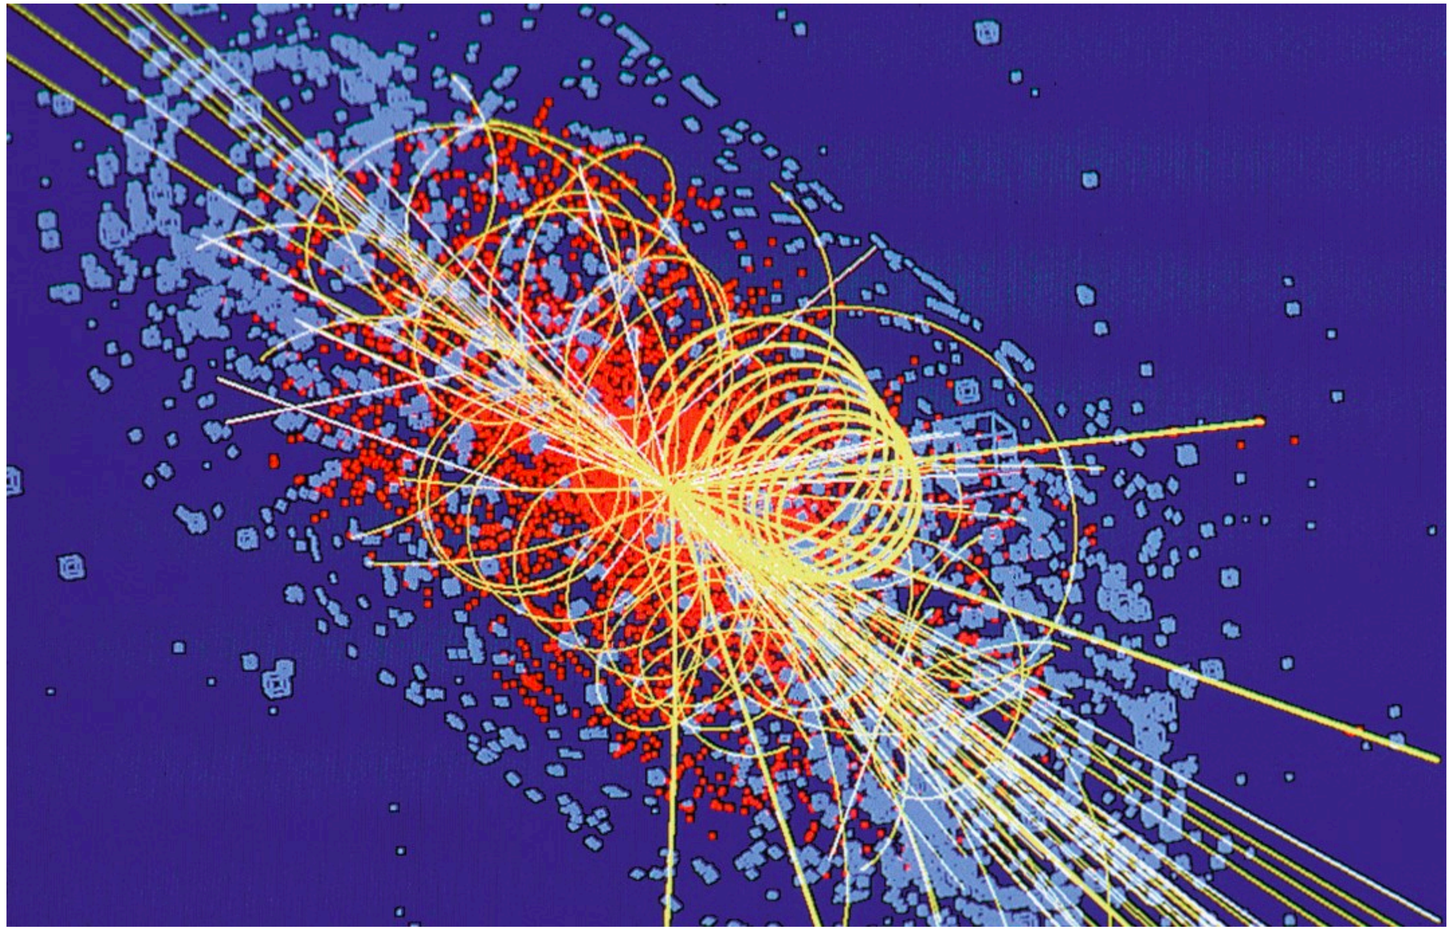
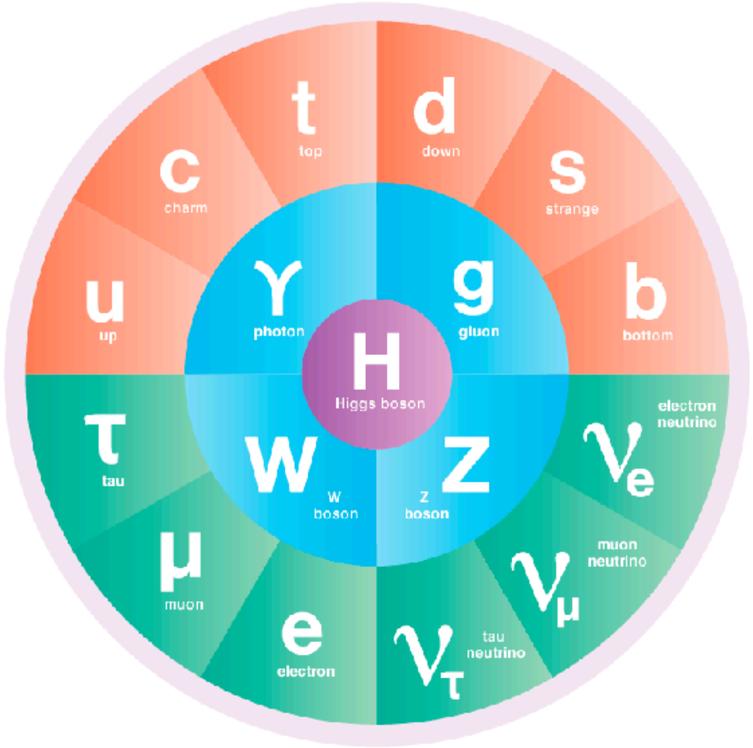
What is Particle Physics?





$$\mathcal{L} = -\frac{1}{4} F_{\mu\nu} F^{\mu\nu}$$

$$+ i\bar{\Psi}\not{D}\Psi + h.c.$$

$$+ \bar{\Psi}_i y_{ij} \Psi_j \phi + h.c.$$

$$+ |D_\mu \phi|^2 - V(\phi)$$

A bit of history…

- Physicists today claim to know what “everything” is made up of — the Standard Model. How did we get here?

Wie der Ueberbringer dieser Zeilen, den ich huldvollst ansuhören bitte, Ihnen des näheren auseinandersetzen wird, bin ich angesichts der "falschen" Statistik der N- und Li-6 Kerne, sowie des kontinuierlichen beta-Spektrums auf einen verzweifelten Ausweg verfallen um den "Wechselsatz" (1) der Statistik und den Energiesatz zu retten. Nämlich die Möglichkeit, es könnten elektrisch neutrale Teilchen, die ich Neutronen nennen will, in den Kernen existieren, welche den Spin 1/2 haben und das Ausschliessungsprinzip befolgen und sich von Lichtquanten ausserdem noch dadurch unterscheiden, dass sie nicht mit Lichtgeschwindigkeit laufen. Die Masse der Neutronen müsste von derselben Grössenordnung wie die Elektronenmasse sein und jedenfalls nicht grösser als 0,01 Protonenmasse.- Das kontinuierliche beta- Spektrum wäre dann verständlich unter der Annahme, dass beim beta-Zerfall mit dem Elektron jeweils noch ein Neutron emittiert wird, derart, dass die Summe der Energien von Neutron und Elektron konstant ist.

- Due to the nature of these diagrams though, any new mass scale above the weak scale should pull the Higgs boson mass to be very, very large.
- Why then, do we see it to be so small?

$$\Delta m_H^2 \approx -\frac{y_t^2}{8\pi^2}\Lambda^2 + \cdots$$

Solution: Supersymmetry

Solution: Supersymmetry

- Every standard model particle has a super-symmetric partner. These superparticles perfectly cancel out all of these quantum corrections to the Higgs mass.

- Many theories of supersymmetry also include a stable particle that can explain the observed Dark Matter in the universe.

- Supersymmetric theories also may help point to a “theory of everything”, where all of the observed “low-energy” forces are unified into one at high energy.

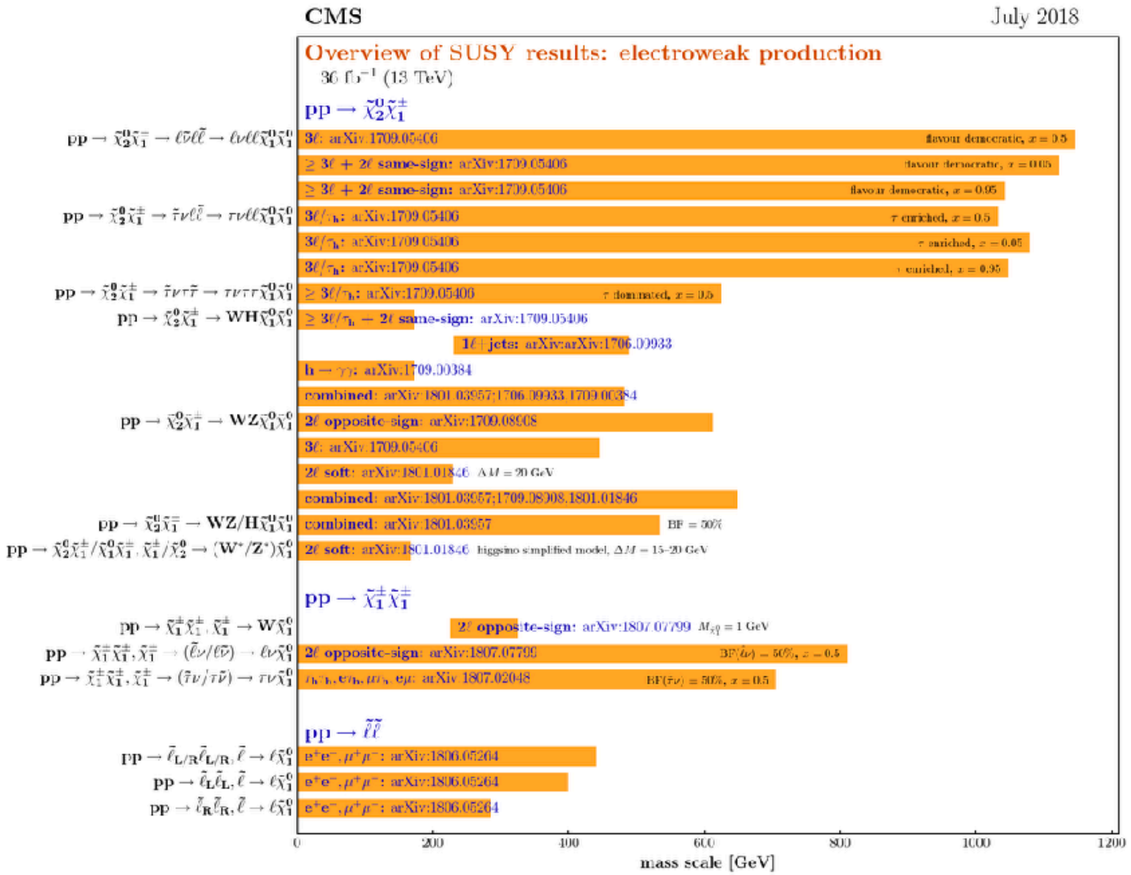
SUSY Searches at the LHC

SUSY Searches at the LHC



Selection of observed limits at 95% C.L. (theory uncertainties are not included). Probe up to the quoted mass limit for light LSPs unless stated otherwise. The quantities ΔM and x represent the absolute mass difference between the primary sparticle and the LSP, and the difference between the intermediate sparticle and the LSP relative to ΔM, respectively, unless indicated otherwise.

*Only a selection of the available mass limits on new states or phenomena is shown. Many of the limits are based on simplified models, c.f. refs. for the assumptions made.

Many, many different ways to search for SUSY at colliders. ATLAS and CMS are the two, powerful, all-purpose detectors at the Large Hadron Collider. To date, no evidence for SUSY has been found.
