## Transverse single spin asymmetry in $J/\psi$ Production in $p\vec{p}$ interactions at SpinQuest

Wednesday, 18 August 2021 14:45 (15 minutes)

In the E1039/SpinQuest experiment at Fermi National Accelerator Laboratory, the Main Injector beam of 120 GeV protons will be incident upon a transversely polarized proton ( $\text{NH}_3$ ) target, and we will observe  $\mu^+\mu^-$  pairs from charmonium and Drell-Yan production. We expect that the  $J/\psi$  and  $\psi'$  will be produced by a mixture of  $q\bar{q}$  and  $gg$  interactions. Due to the high cross section of these channels and the very high luminosity of this experiment ( $\approx 10^{36} \text{ cm}^{-2}\text{s}^{-1}$ ) we will be able to get enough statistics in a few weeks to report on the transverse single spin asymmetry (TSSA) in the process  $p + p^\uparrow = J/\psi + X$ . In order to get enough statistics within a short period of time, we will optimize the detector setup including the relative polarity of the spectrometer's two magnetic fields. Such asymmetries will shed light on the  $J/\psi$  production mechanism, a long-standing question in QCD, while also exploring the transverse structure of the proton.
