# Introduction

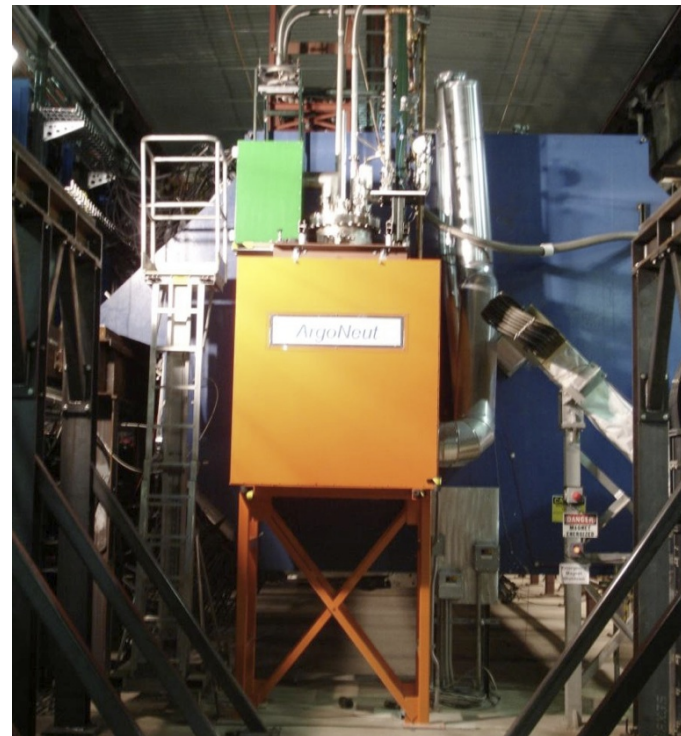

Heavy neutral leptons and heavy QCD axions are both proposed extensions to the Standard Model:

- provide possible explanations for various unresolved puzzles
- heavy neutral leptons: neutrino mass, dark matter...
- heavy QCD axions: strong CP problem, axion quality problem...

Could be produced in neutrino beams, and their decays searched for in neutrino detectors:

- such as the ArgoNeuT detector

This talk will present searches for heavy neutral leptons and heavy QCD axions performed with the ArgoNeuT experiment

- The ArgoNeuT experiment
- Models, production and decay
- Simulation and signature
- Selection
- Backgrounds and systematics
- Results

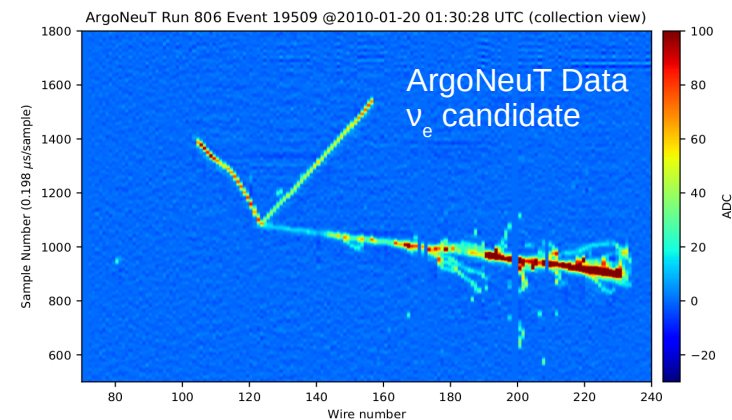

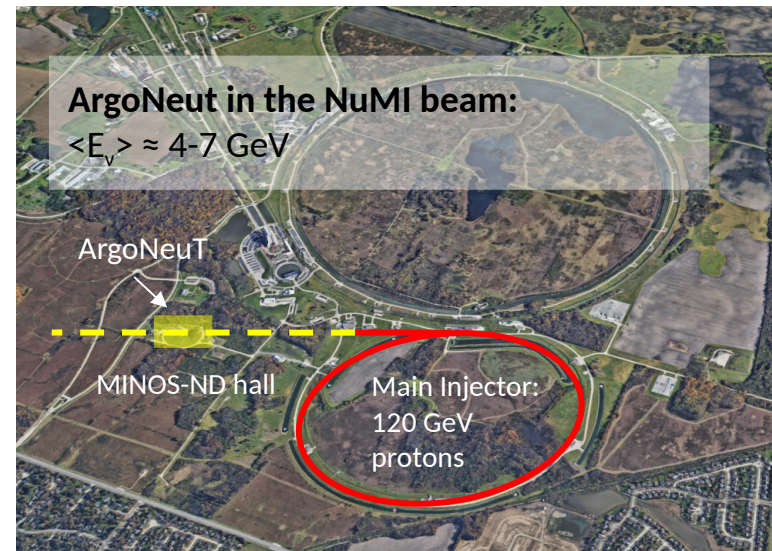

# The ArgoNeuT experiment

First Liquid Argon Time Projection Chamber (LArTPC) in a neutrino beam in the US:

- located along the NuMI beam, ~1km from the beam target
- collected data 2009-2010, ~4.5 month run
- $1.25 \times 10^{20}$  POT, ~7000 neutrino interactions

Designed as a test experiment... but producing physics results:

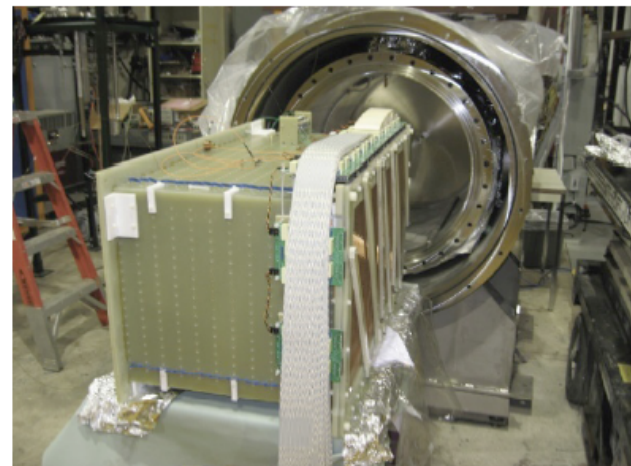

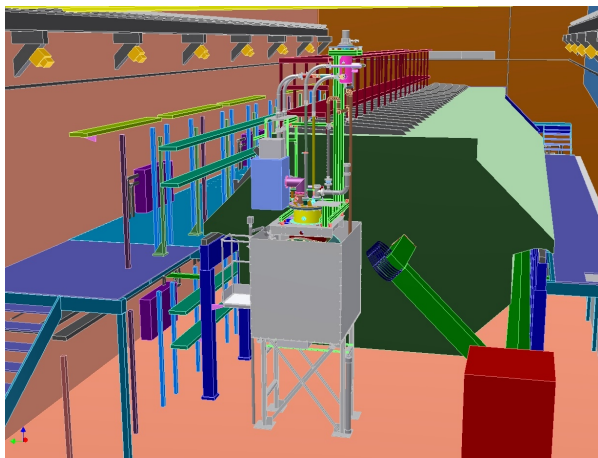

- several first  $\nu$ -Ar cross-section measurements
- BSM searches: millicharged particles, heavy neutral leptons, heavy QCD axions
- along with extensive detector R&D

# The ArgoNeuT detector

## 0.24 ton LArTPC:

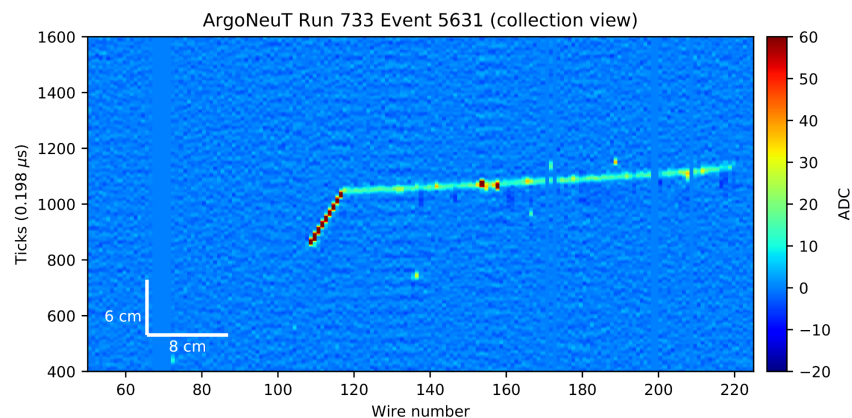

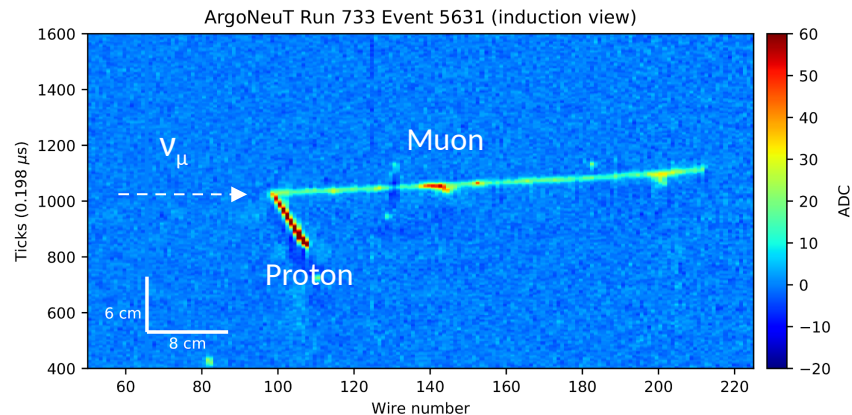

- 40(h)x47(w)x90(l) cm<sup>3</sup> instrumented volume
- two wire planes collect drifted ionisation charge
- 4mm wire spacing

## Upstream of the MINOS near detector:

- large magnetised steel and scintillator strip spectrometer
- used to identify muons – tracks exiting ArgoNeuT are matched with tracks reconstructed in the MINOS-ND

# LArTPC technology: 3D imaging and calorimetry

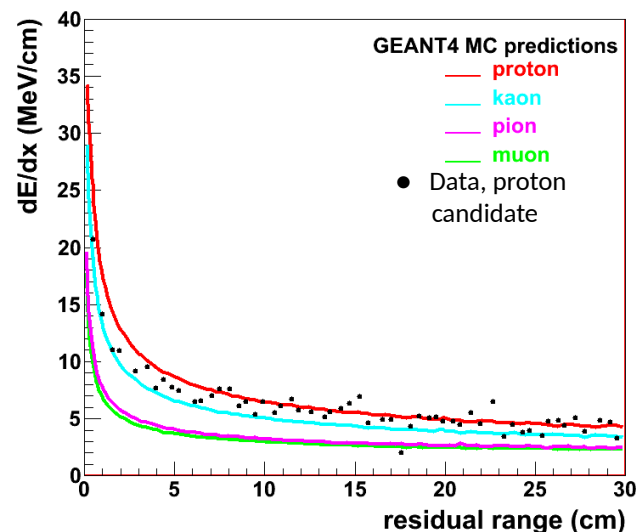

Two 2D views, with  $\sim 4$  mm scale resolution

→ 3D Track/Shower reconstruction

Total charge proportional to the deposited energy

→ Calorimetry

Particle identification based on  $dE/dx$ :

# Heavy neutral lepton and heavy QCD axion models

## Heavy neutral lepton (HNL) model:

- simple extension to SM introducing a HNL,  $N$
- mass  $m_N \sim 100 \text{ MeV} - 1 \text{ GeV}$  and mixes with SM neutrinos via new non-zero mixing angle
- consider tau-coupled scenario, i.e.  $|U_{\tau N}|^2 \neq 0$  and  $|U_{eN}|^2 = |U_{\mu N}|^2 = 0$

P. Coloma et al. Eur. Phys. J. C, 81(1):78, 2021

## Heavy QCD axion model:

- introduce heavy QCD axion,  $a$
- consider couplings with gluons + other SM gauge bosons and leptons
- mass  $m_a \sim 100 \text{ MeV} - 1 \text{ GeV}$  and mixing angle  $\theta_a$  with the SM neutral pseudoscalar mesons

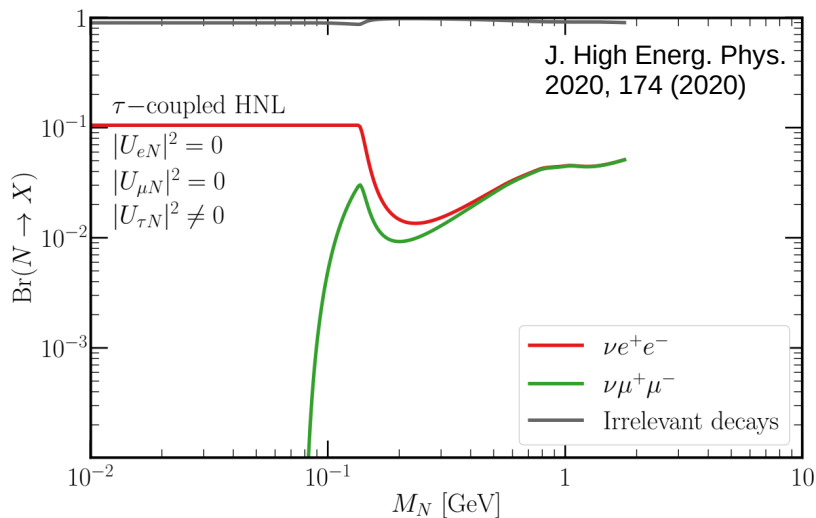

K. Kelly, S. Kumar and Z. Liu Phys. Rev. D 103 (2021) 9, 095002

Very different models... but can produce similar decay signatures in ArgoNeuT

# Decay modes

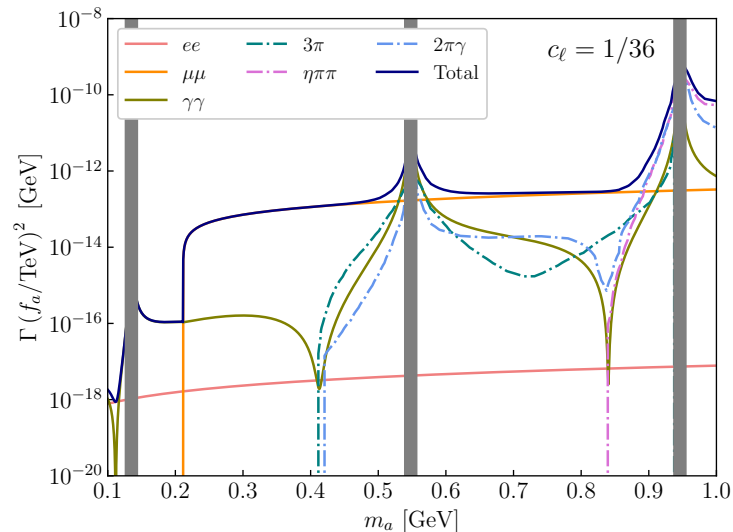

## Heavy neutral leptons (tau-coupled):

- decay to  $\nu e e$  and  $\nu \mu \mu$  + various non-detectable channels such as  $\nu \nu \nu$
- in ArgoNeuT search for:  $N \rightarrow \nu_\tau + \mu^+ + \mu^-$

## Heavy QCD axions:

- decay to  $ee$ ,  $\mu\mu$ ,  $\gamma\gamma$  + hadronic modes
- contributions depend on axion-lepton coupling,  $c_\ell$ : two benchmark scenarios  $c_\ell = 1/36$  and  $c_\ell = 1/100$
- in ArgoNeuT search for:  $a \rightarrow \mu^+ + \mu^-$

# Production in the NuMI beam

Heavy neutral leptons:

- proton—fixed-target collisions produce flux of D and D<sub>s</sub> mesons
- D / D<sub>s</sub> decay to τ leptons, then subsequently decay to tau-coupled HNLs

$$D_{(s)}^{+/-} \rightarrow \tau^{+/-} + \nu_{\tau}$$

$$\tau^{+/-} \rightarrow N + X^{+/-} \quad \text{where } X^{+/-} \text{ are SM particles e.g. } \pi^{+/-}$$

Heavy QCD axions

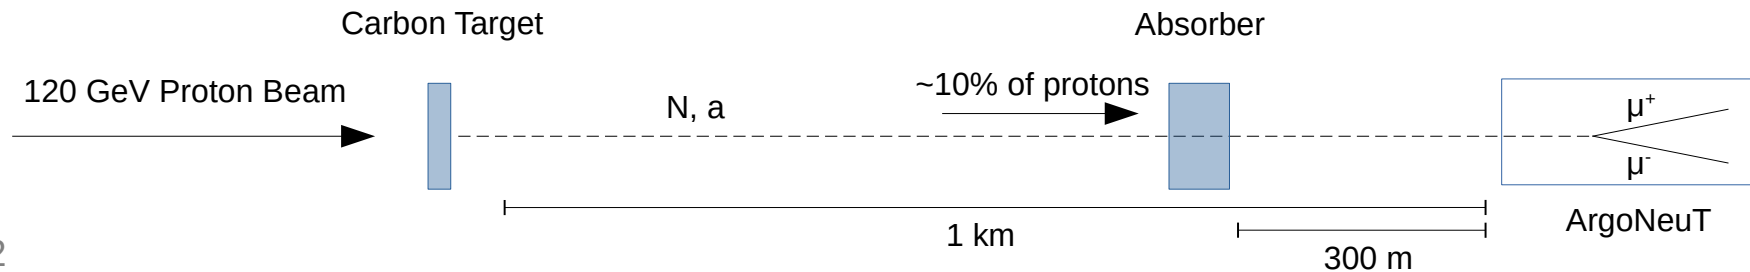

- proton—fixed-target collisions produce flux of π<sup>0</sup>, η and η' mesons
- non-zero mixing angle, θ<sub>aM</sub>, results in flux of axions

$$\theta_{aM} = \frac{f_{\pi}}{f_a} \frac{C_{aM}}{m_a^2 - m_M^2}$$

$$\text{where } M = \pi, \eta, \eta'$$

Mass range ~100 MeV – 1 GeV

~10% of protons reach the NuMI absorber, where production also occurs

# Why perform these searches with ArgoNeuT?

Exposed to high-energy 120 GeV NuMI beam:

- enables production of heavy neutral leptons and heavy QCD axions with masses up to approximately the 1 GeV scale

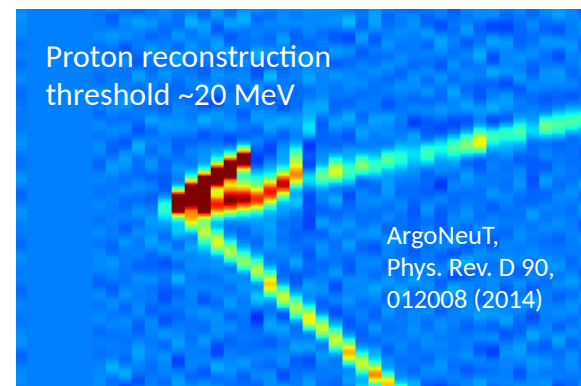

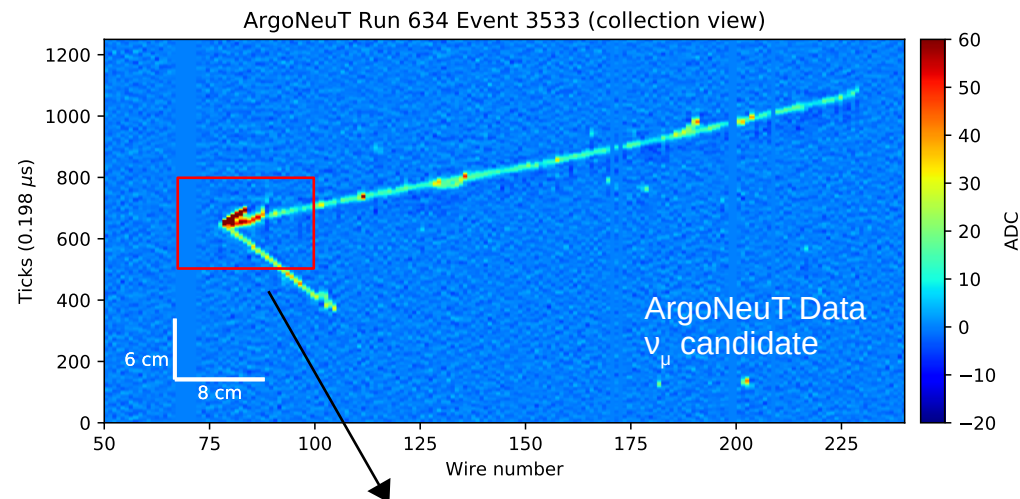

LArTPC detector technology:

- excellent vertex identification and reconstruction of low energy particles
- allows identification and removal of backgrounds

Upstream of the MINOS near detector:

- magnetic field allows muon charge reconstruction
- aids distinguishing pions and muons, difficult in LArTPCs

Ideal combination of detectors to search for  $\mu^+ \mu^-$  signature

# HNL and axion simulation

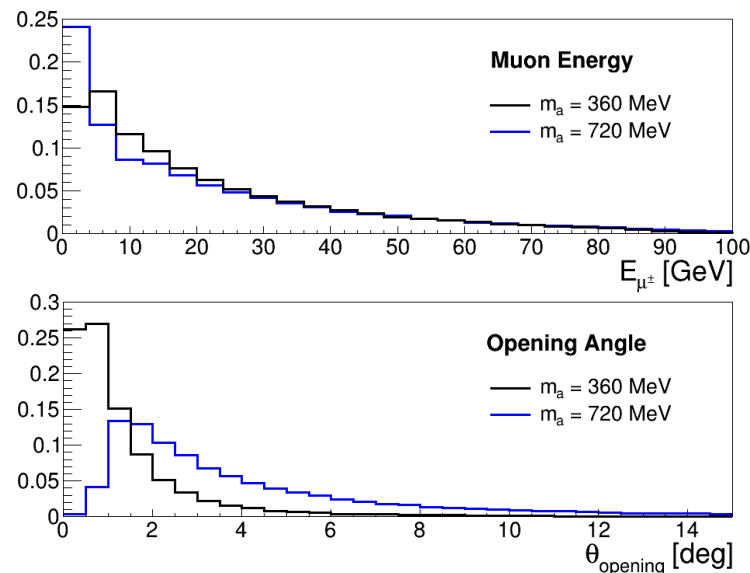

Dedicated simulations performed for both heavy neutral leptons and heavy QCD axions:

- production using pythia8 + standard ArgoNeuT and MINOS simulation and reconstruction chains
- resulting muons energetic and highly forward-going – may be reconstructed as overlapping in ArgoNeuT

## Heavy neutral leptons

## Heavy QCD axions

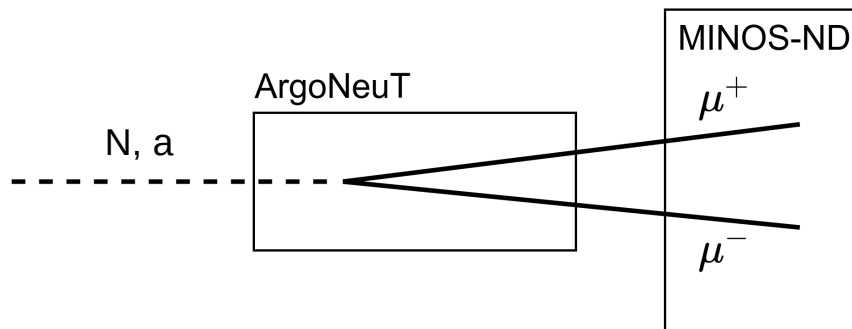

# Signatures in ArgoNeuT

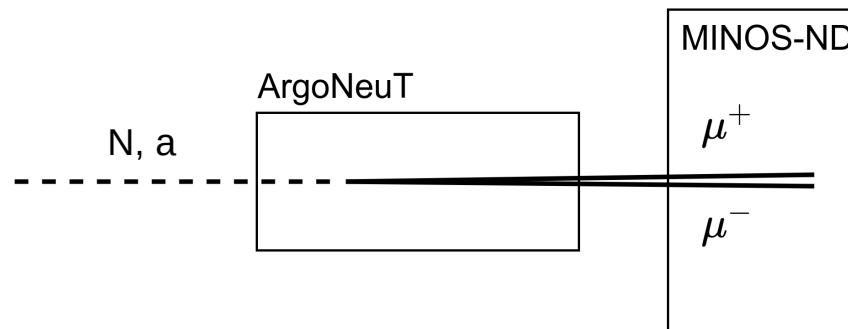

Consider two different signatures, depending on how forward going the muons are:

- Signature 1: two MIP tracks in ArgoNeuT, match to two tracks in MINOS-ND
- Signature 2: single double-MIP dE/dx track in ArgoNeuT, matches to two tracks in MINOS-ND

*Two-track Event*

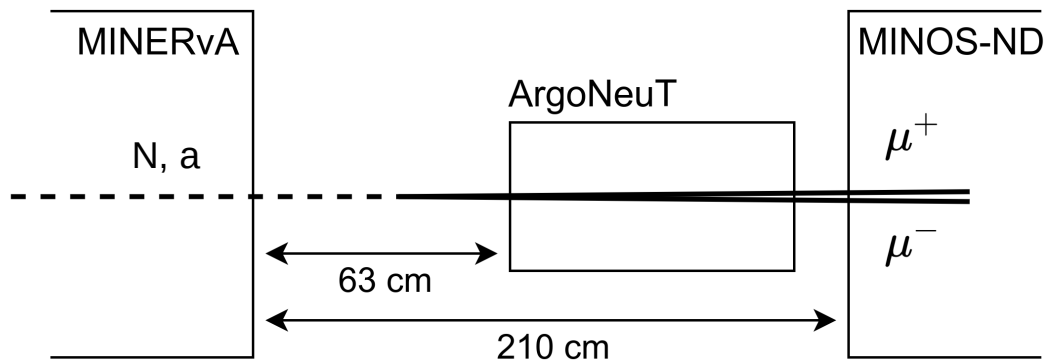

*Double-MIP Event*

# Decays in the cavern upstream of ArgoNeuT

Also consider decays occurring in the cavern upstream of ArgoNeuT:

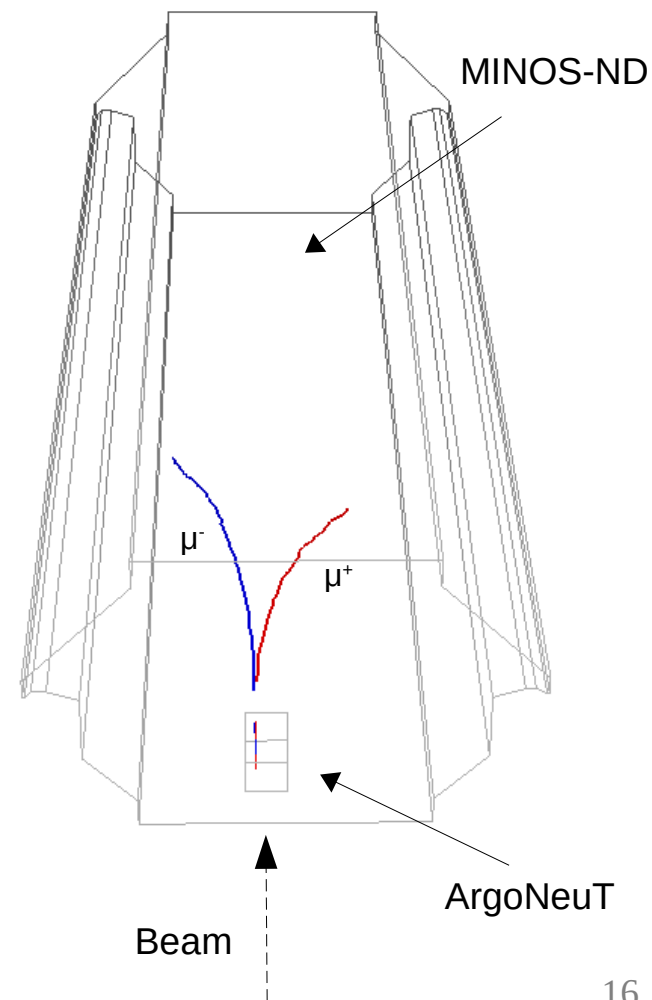

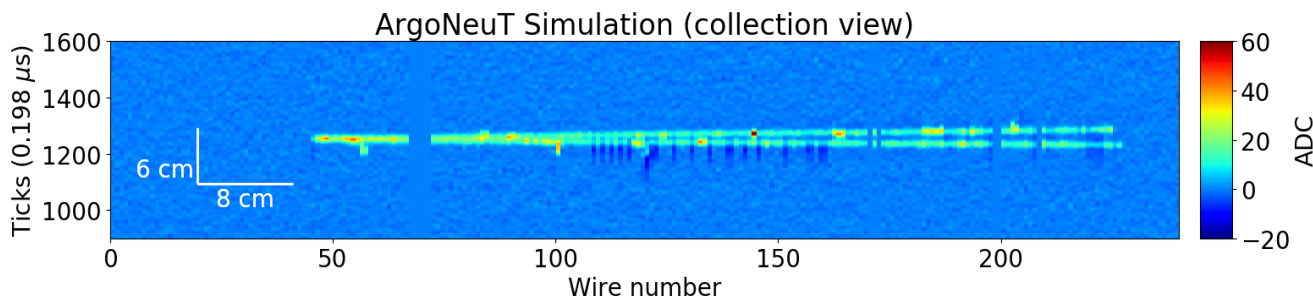

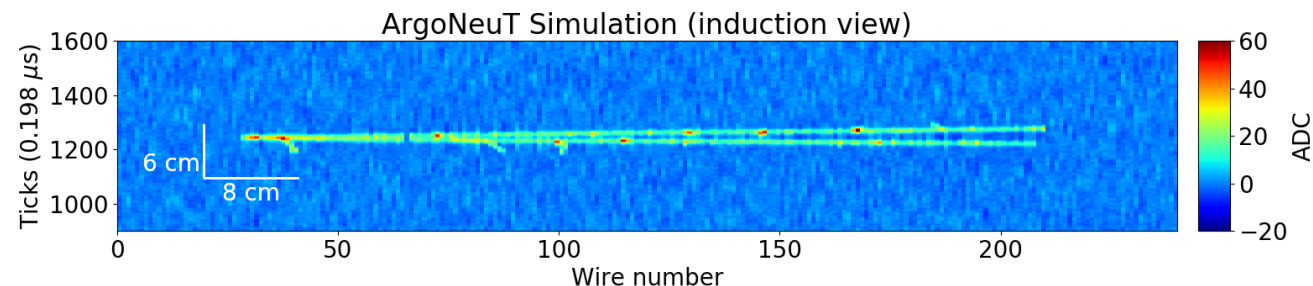

- region between ArgoNeuT and end of MINERvA detector (under construction during ArgoNeuT running)
- select double-MIP signature only, distinct from background neutrino-induced muons

# Simulated decay: two-track topology

Example simulated *two-track* signature event:

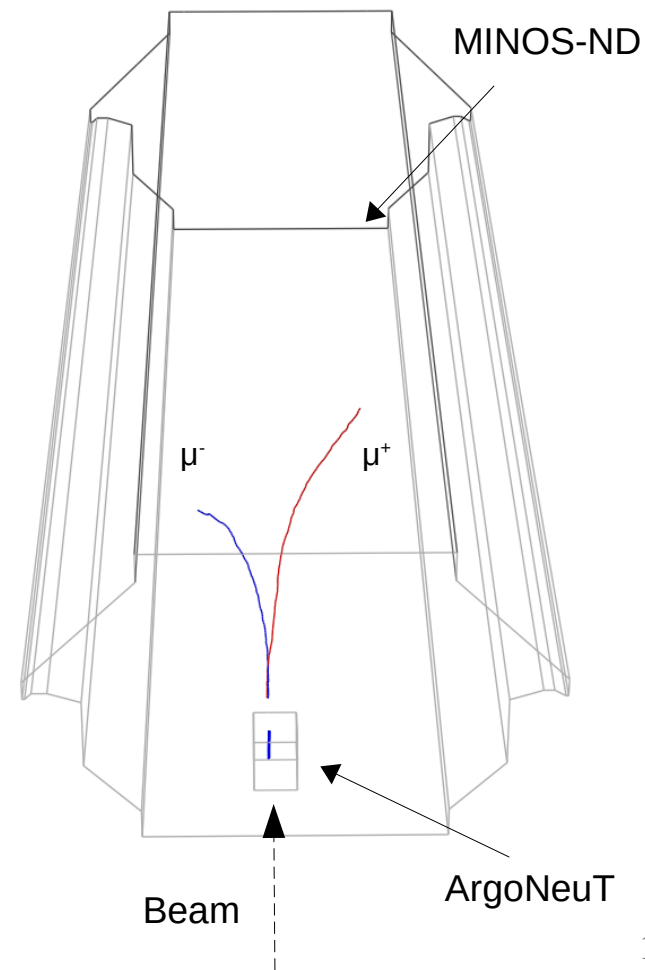

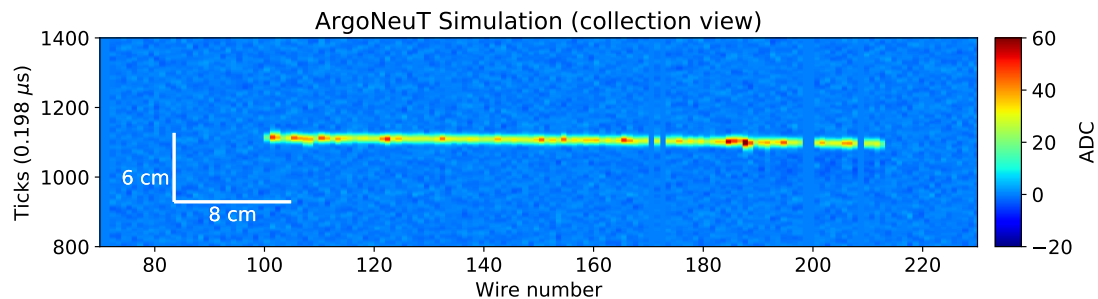

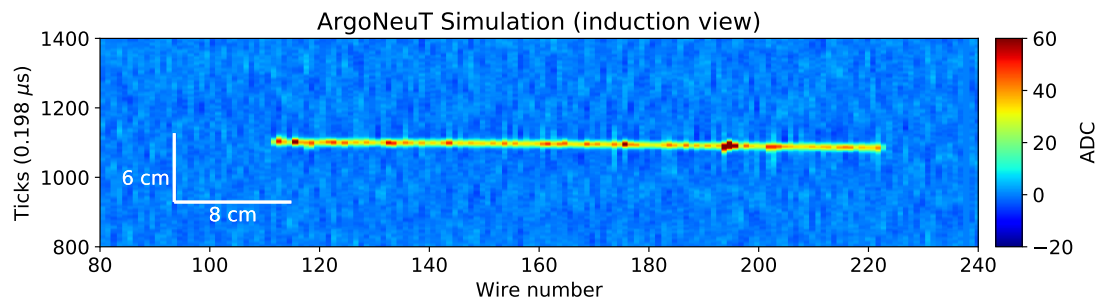

- two distinct muon tracks in ArgoNeuT that match to MINOS-ND

# Simulated decay: double-MIP topology

Example simulated *double-MIP* signature event:

- single track in ArgoNeuT that matches to two tracks in MINOS-ND

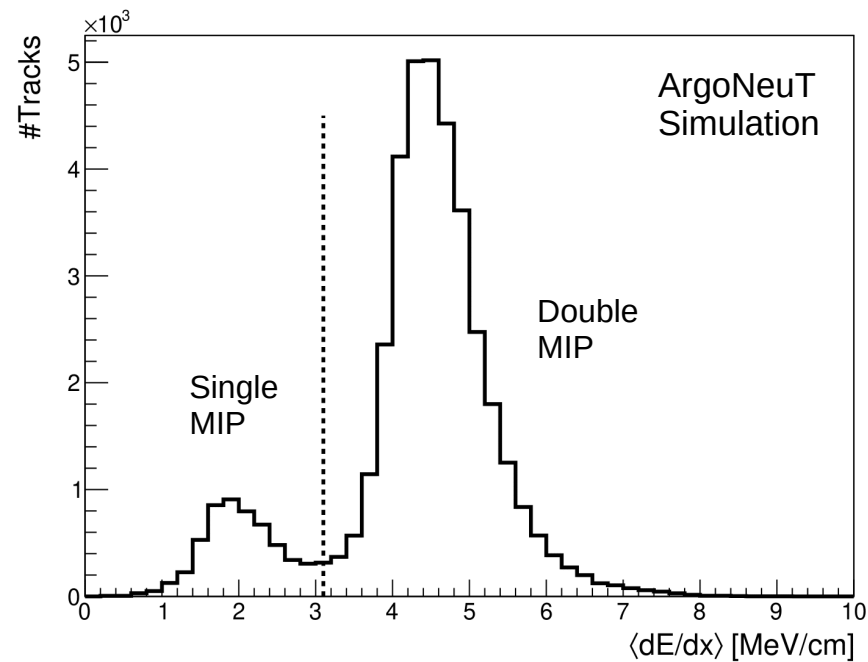

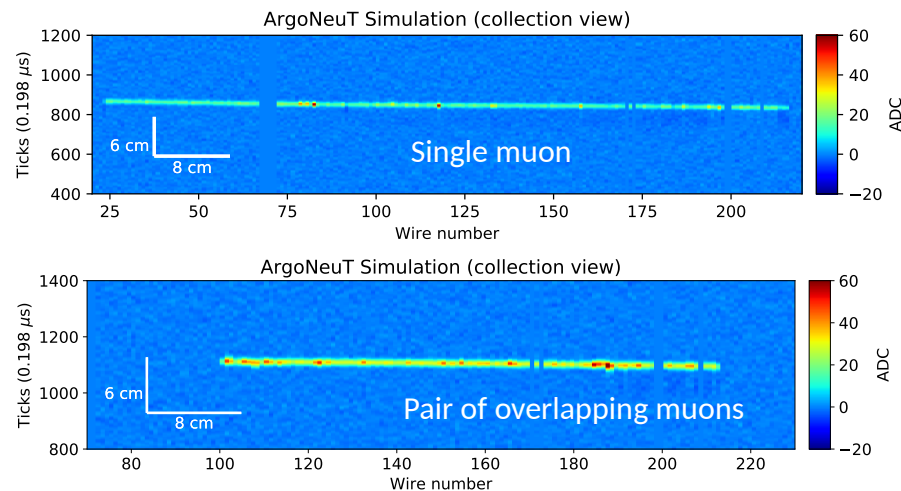

- The ArgoNeuT experiment
- Models, production and decay
- Simulation and signature
- **Selection**
- Backgrounds and systematics
- Results

# Identifying overlapping muon pairs

Strongest identifier of whether overlapping muons are present provided by the  $dE/dx$ :

- minimally ionising particle  $dE/dx \sim 2$  MeV/cm
- overlapping muons  $\sim 2 \times$  MIP  $dE/dx$

MIP and double-MIP tracks easily distinguishable

# Selection in ArgoNeuT

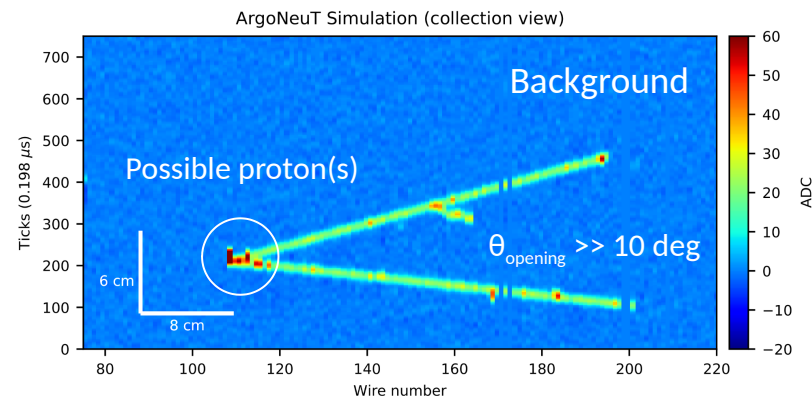

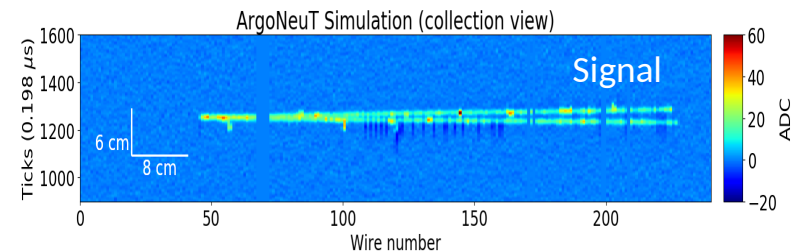

## Two-track signature:

- two tracks that originate from a common vertex within fiducial volume + exit towards MINOS-ND
- both tracks have mean  $dE/dx < 3.1$  MeV/cm
- small opening angle between them

## Double-MIP signature:

- $dE/dx > 3.1$  MeV/cm over first 5 cm of track
- small angle with respect to the beam direction

Selections tuned using simulation for each model

# MINOS-ND matching

## MINOS-ND matching:

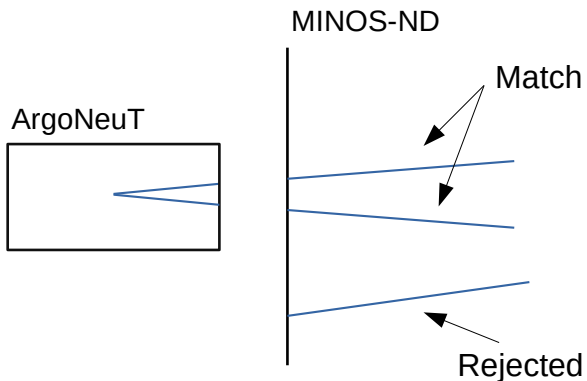

- each ArgoNeuT track projected to start of MINOS-ND
- position and angular offset to each MINOS-ND track calculated, matches if within tolerance

## Selection in MINOS-ND:

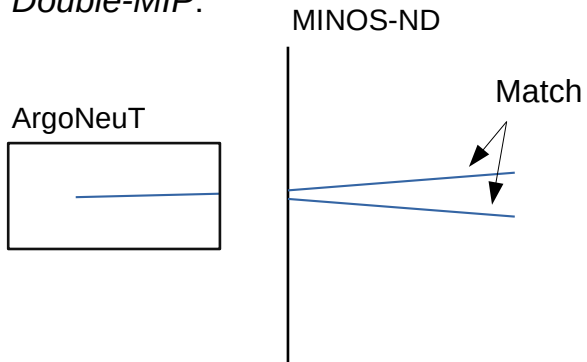

- tracks in-time,  $|\Delta t_0| < 20$  ns
- tracks reconstructed with opposite charges
- both tracks muon-like: track length and MIP dE/dx

As before, selections tuned using simulation for each model

## Two track:

## Double-MIP:

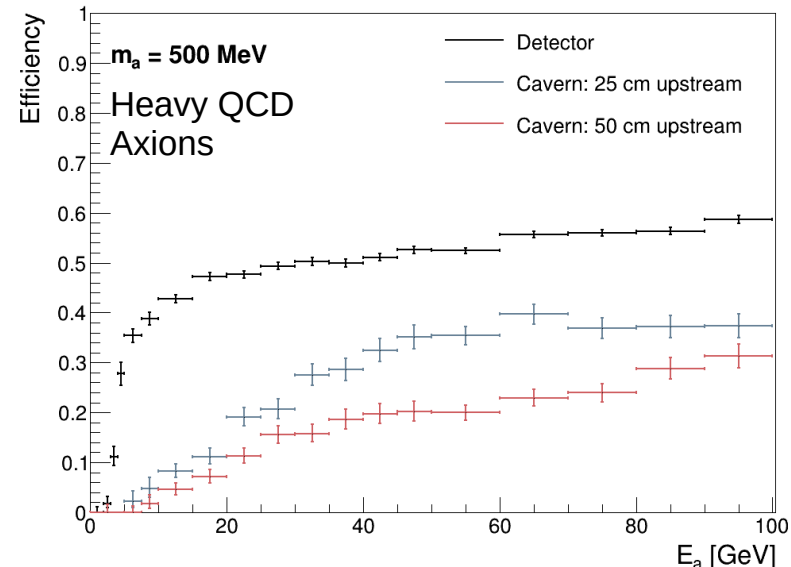

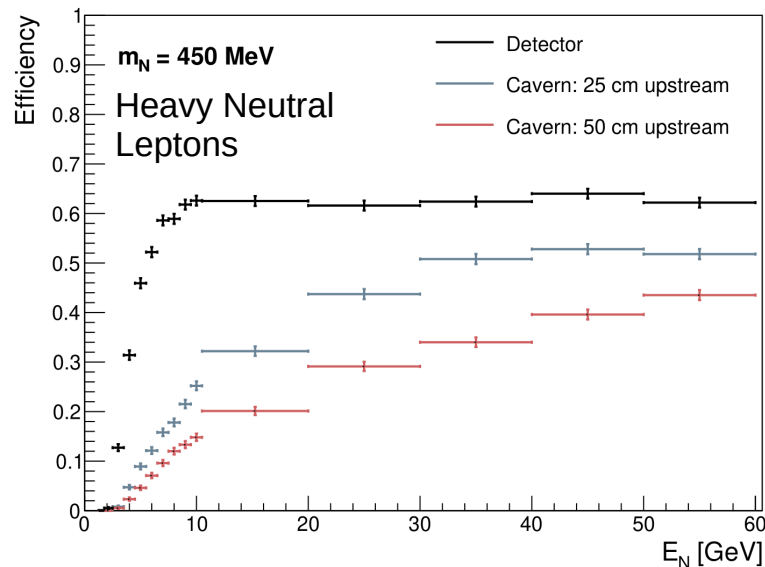

# Selection efficiency

Decays-inside-detector efficiencies:

- ~50-60% at high energies, slightly lower in axion case
- sharp decline at lower energies, muons have insufficient energy to reach the MINOS-ND

Decays-inside-cavern efficiencies lower – only select most forward-going muon pairs

- The ArgoNeuT experiment
- Models, production and decay
- Simulation and signature
- Selection
- **Backgrounds and systematics**
- Results

# Background expectation

Background simulation:

- GENIE neutrino generator (detector and cryostat)
- data-driven model of through-going muons

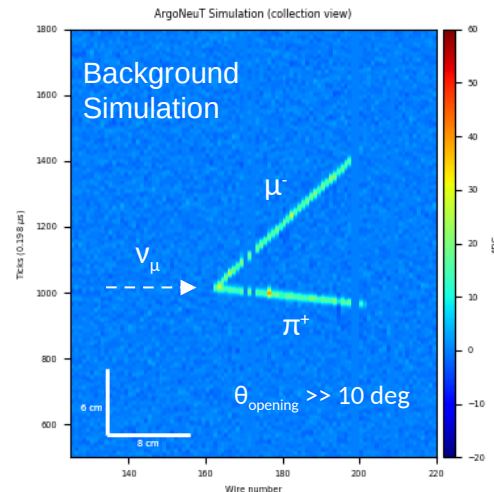

Dominant source of background:

- $\nu_\mu$  interactions with minimal additional vertex activity and/or incorrectly matched additional neutrino-induced through-going muons in MINOS-ND

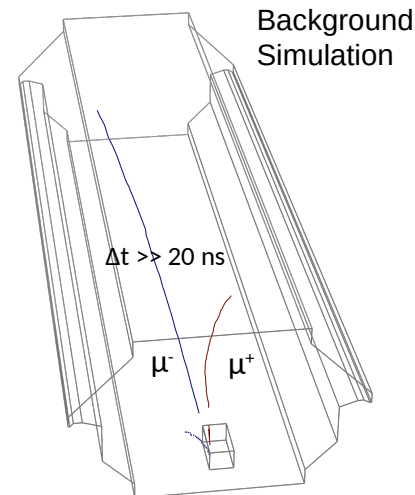

Typically topologically distinct and/or matched to out-of-time tracks in MINOS-ND – can be removed

Total background expectation small – very clean signature:

Model	Predicted Events
Heavy Neutral Leptons	$0.4 \pm 0.2$
Heavy QCD Axions	$0.1 \pm 0.1$

Topologically distinct, opening angle too large

Matched muon tracks out of time, from different interactions/decays

# Systematic uncertainties

## Heavy neutral leptons:

- dominated by uncertainty in HNL flux
- due to uncertainty in  $D / D_s$  production + uncertainty on branching ratio to  $\tau$  leptons

Systematic Uncertainty	Impact [%]
HNL flux	20.8
Reconstruction effects	0.5
Selection efficiency	3.3
Instrumented volume	2.2
POT counting	1.0
Total	21.2

## Heavy QCD axions:

- dominated by uncertainty in axion flux
- primarily due to theoretical uncertainties arising from QCD calculations
- depends on the coupling strengths chosen

Systematic Uncertainty	Impact [%]
Axion flux	~30
Reconstruction effects	0.5
Selection efficiency	3.3
Instrumented volume	2.2
POT counting	1.0
Total	~30.3

# Applying to data

Selections applied to ArgoNeuT data-set:

- 1.25e20 POT, anti-neutrino mode beam

**0 events observed in data**

- consistent with background expectations

Allows exclusion constraints to be set...

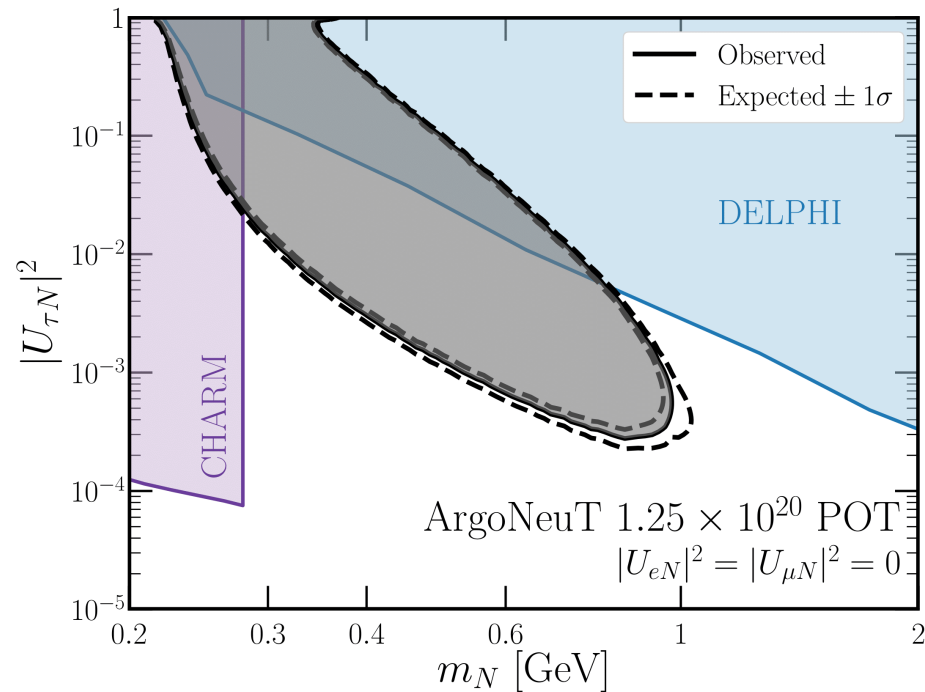

# Heavy neutral leptons

ArgoNeuT HNL constraint:

- region of parameter space excluded at 90% CL (solid black line, gray shaded region)
- uncertainty on expected constraint (dashed line)

Existing limits from CHARM (purple) and DELPHI (blue) also shown

Set new exclusion constraint on tau-coupled HNLs with masses  $m_N = 280 - 970$  MeV

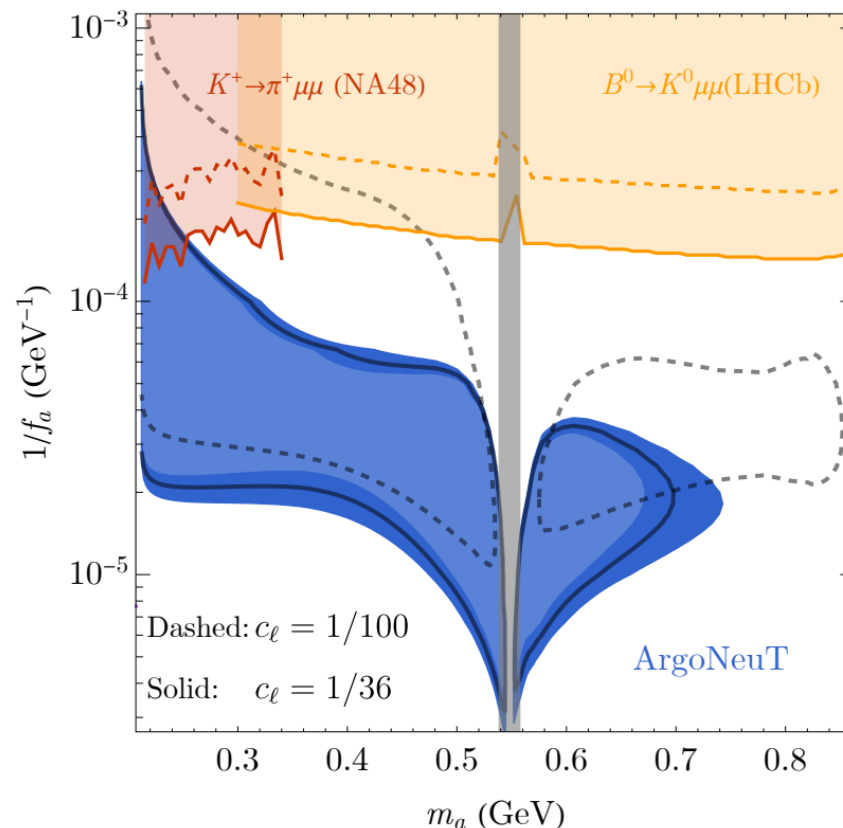

# Heavy QCD axions

ArgoNeuT heavy QCD axion constraint:

- 95% CL exclusion constraints for  $c_l = 1/36$  (solid contour, blue shaded region) and  $c_l = 1/100$  (dashed contour)
- uncertainty on expected constraint shown for  $c_l = 1/36$  (dark blue shaded region)

Existing limits re-cast from NA48 (red) and LHCb (orange) for both benchmark models

Set new exclusion constraints for heavy QCD axions with  $m_a \sim 0.2 - 0.9$  GeV and axion decay constant  $f_a \sim 10$  TeV

# Summary and conclusions

Searches for heavy neutral leptons and heavy QCD axions have been performed using the ArgoNeuT detector:

- produced in NuMI neutrino beam from  $\tau^\pm$  decay (HNLs) and meson-mixing (axions)
- heavy neutral lepton decay signature:  $N \rightarrow \nu \mu^+ \mu^-$
- heavy QCD axion decay signature:  $a \rightarrow \mu^+ \mu^-$

Observe 0 events in ArgoNeuT data, allowing new exclusion constraints to be set:

- tau-coupled heavy neutral leptons:  $m_N = 280 - 970$  MeV
- heavy QCD axions:  $m_a = 0.2 - 0.9$  GeV, with  $f_a \sim 10$  TeV

First searches for each of these models in LArTPC neutrino detectors:

- techniques developed could be employed in future searches using LArTPC detectors, e.g. DUNE

Heavy neutral lepton search: Phys. Rev. Lett. 127, 121801 (2021) [arXiv: 2106.13684]

Heavy QCD axion search: arXiv: 2207.08448

# Back-up

# Heavy Neutral Lepton and Heavy QCD Axion energies

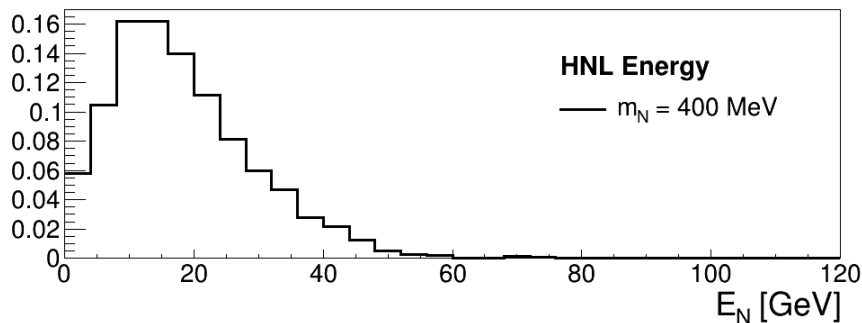

Tau-coupled Heavy Neutral Leptons:

- average energy  $\sim 20$  GeV, produced up to around 60 GeV

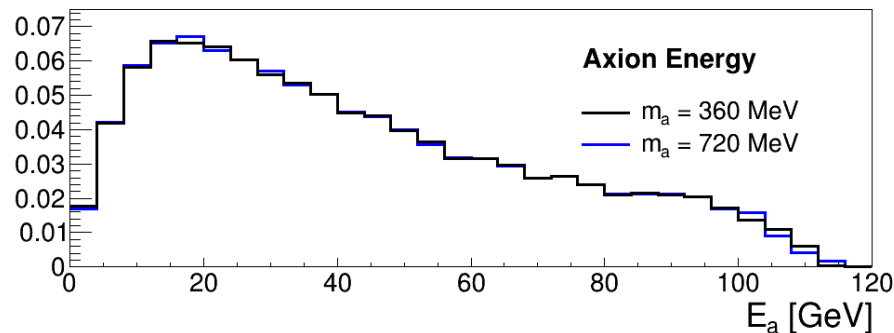

Heavy QCD Axions:

- average energy  $\sim 40$  GeV, production possible up to nearly beam energy

Heavy Neutral Leptons

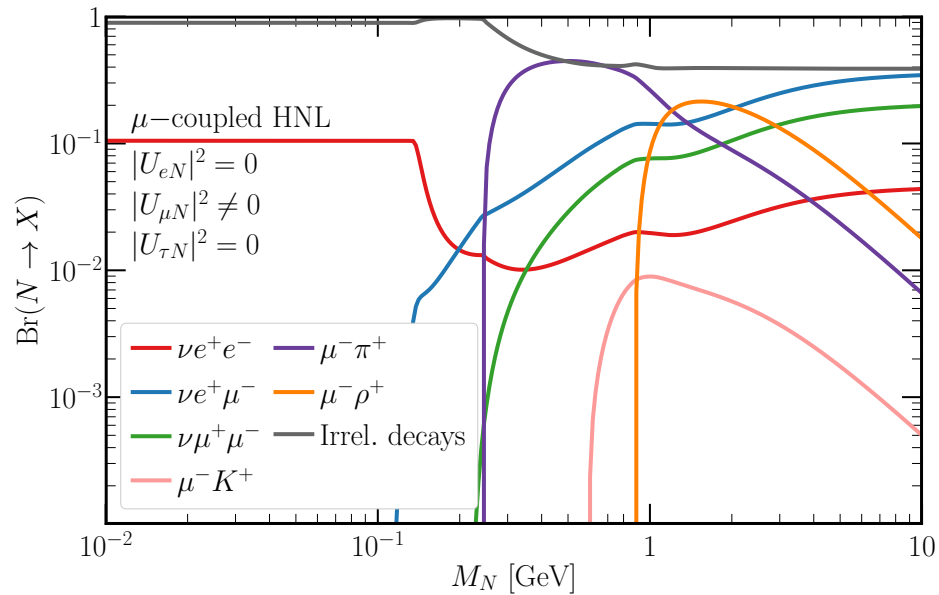

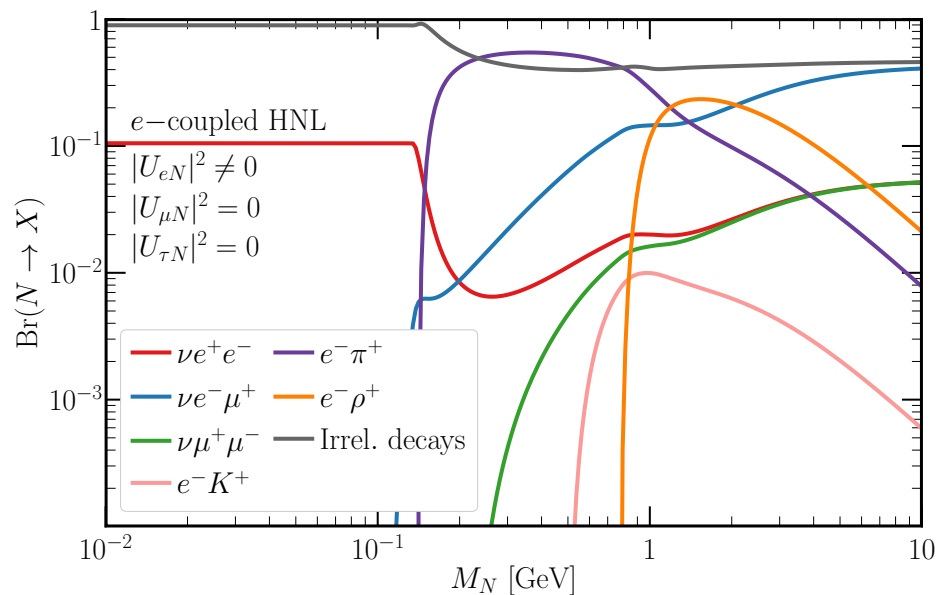

Heavy QCD Axions

# Electron/muon-coupled HNLs: branching ratios

HNL scenarios where  $|U_{eN}|^2 \neq 0$  or  $|U_{\mu N}|^2 \neq 0$ , in each case assuming mixing to the other flavors is zero

Dimuon channel subdominant to  $e\pi$  (electron-coupled) and  $\mu\pi$  (muon-coupled) in mass range of interest – ArgoNeuT has less sensitivity to these scenarios

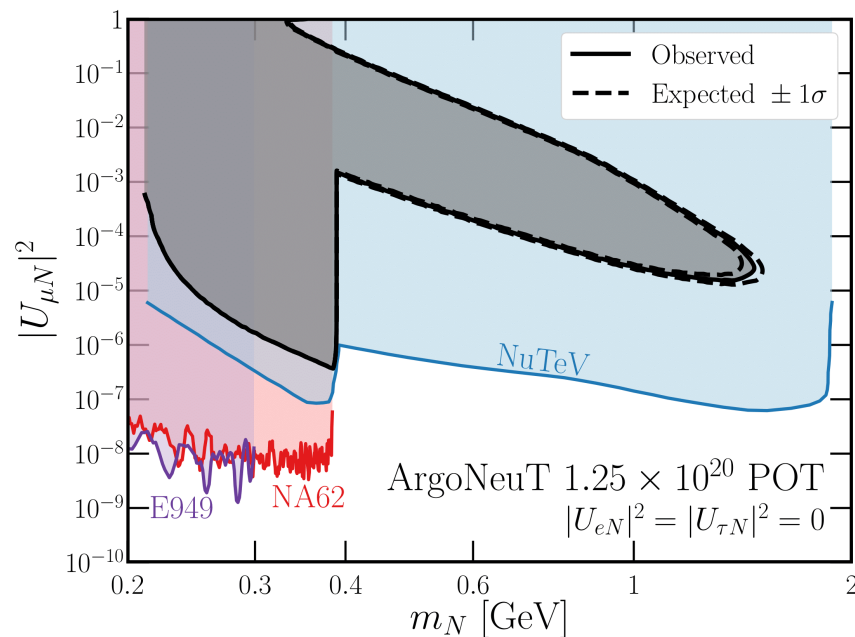

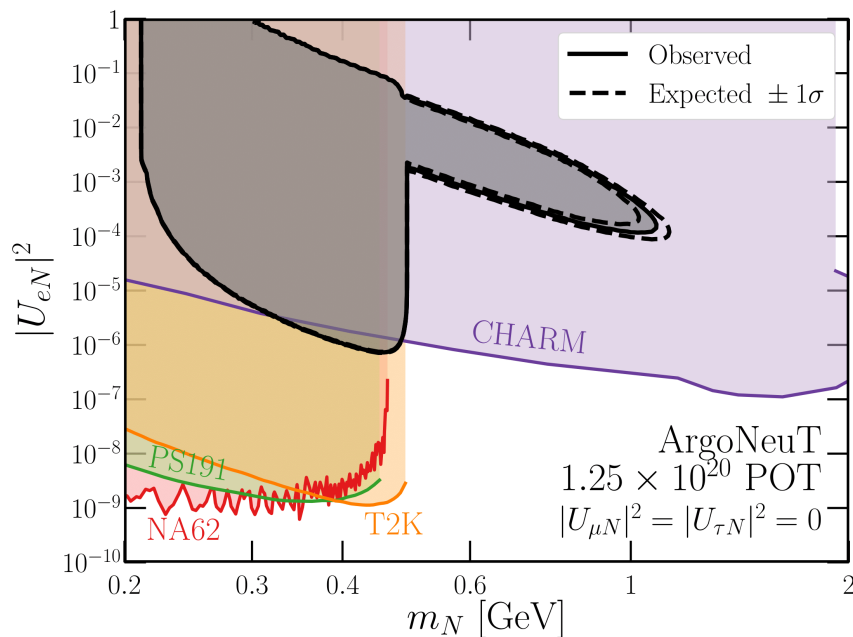

# Electron/muon-coupled HNLs: sensitivity

HNL scenarios where  $|U_{eN}|^2 \neq 0$  or  $|U_{\mu N}|^2 \neq 0$ , in each case assuming mixing to the other flavors is zero

Parameter space excluded at 90% CL (solid black line)

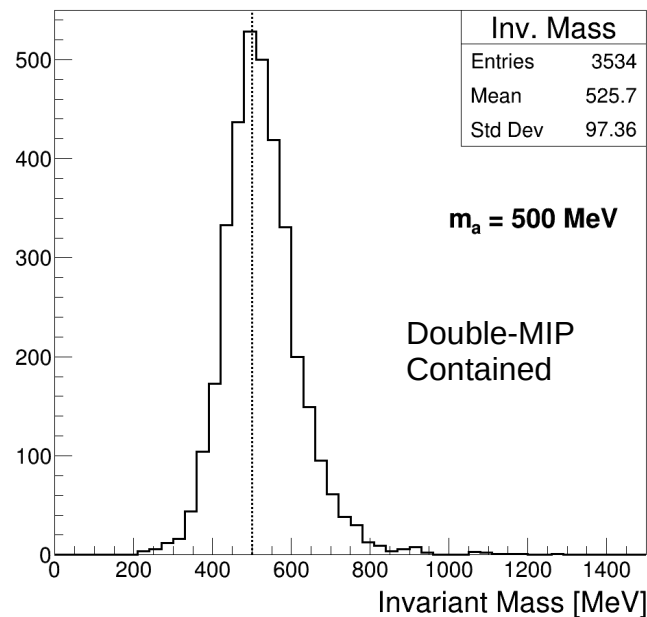

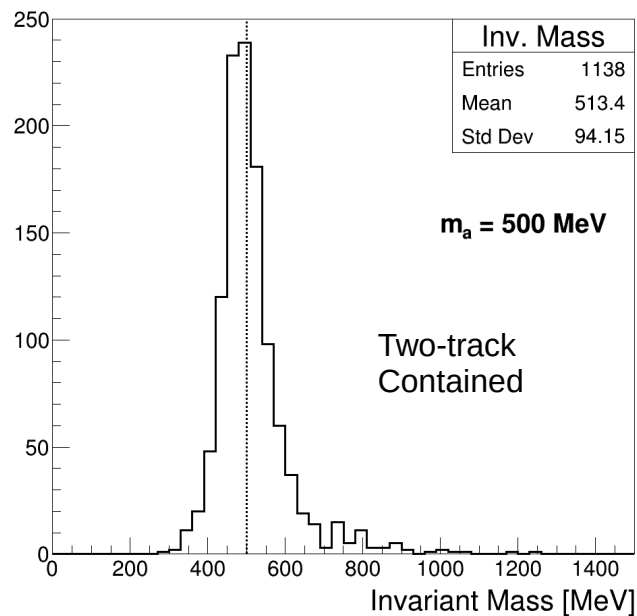

ArgoNeuT sensitivity to these models is significantly poorer than existing limits

# Heavy QCD Axion invariant mass

Heavy QCD Axion decay two-body – invariant mass could provide powerful tool if signal observed:

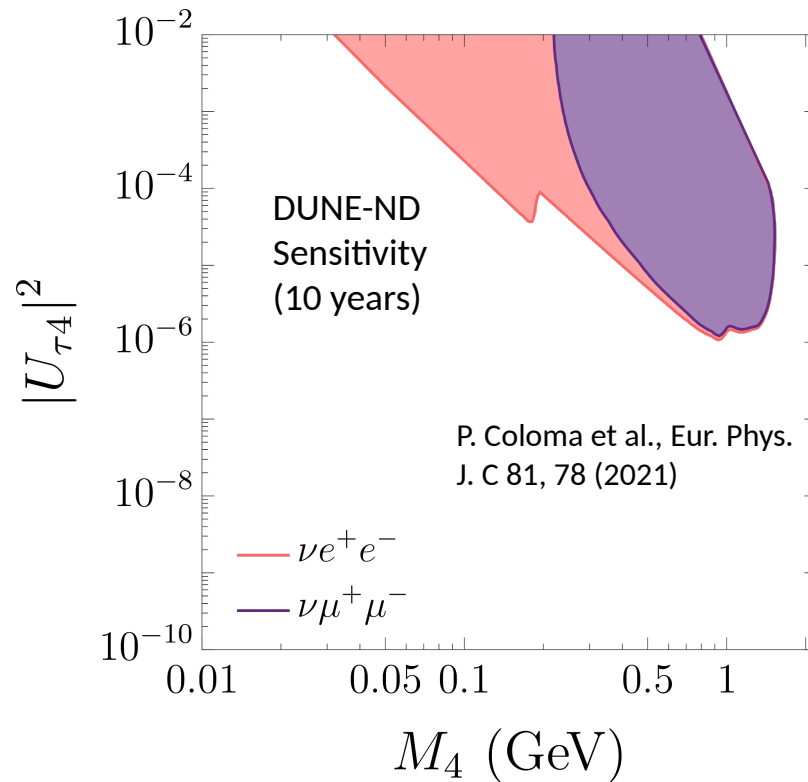

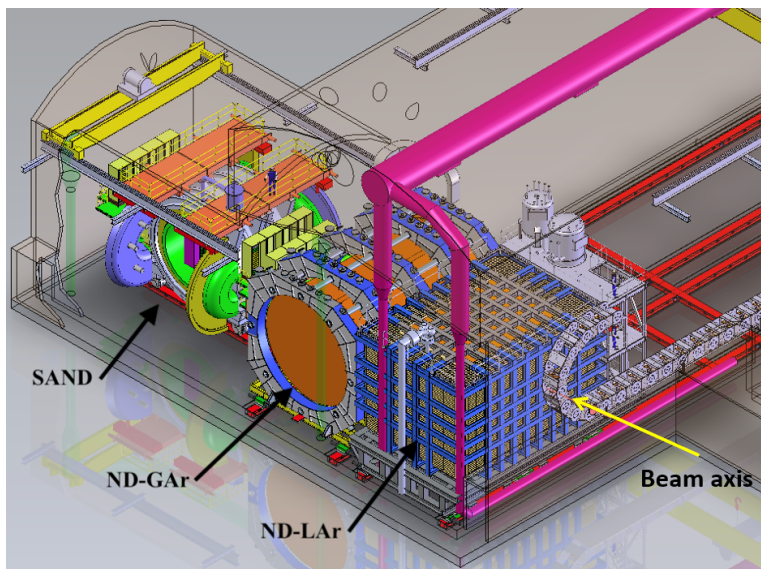

- muon trajectories reconstructed in ArgoNeuT and momentum in the MINOS-ND
- axion invariant mass resolution:  $\sim 100$  MeV contained in MINOS-ND,  $\sim 200$  MeV exiting MINOS-ND

# Future searches for tau-coupled HNLs in LArTPCs

DUNE near detector:

- sensitive to large region of unexplored phase space
- modular LArTPC and magnetised GArTPC -- could employ similar techniques to search for  $\mu^+ \mu^-$

# Future searches for heavy QCD axions in LArTPCs

DUNE near detector also sensitive to heavy axions:

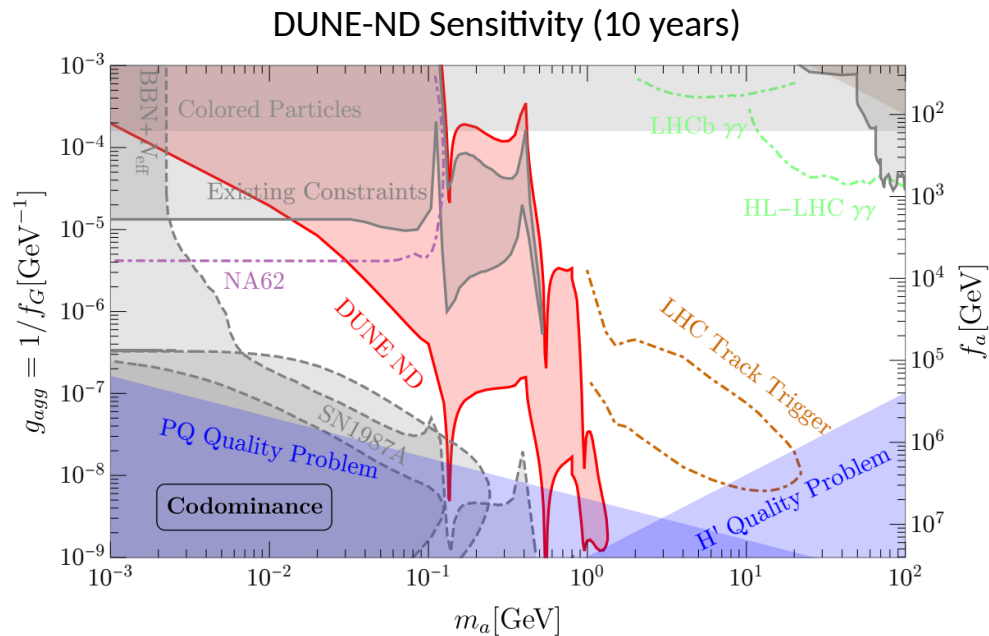

- able to probe large region of parameter space

SBN detectors (SBND, MicroBooNE, ICARUS):

- either using off-axis NuMI beam, or could be sensitive to lower masses using 8 GeV BNB beam

Other “axion-like” models also been considered:

- ArgoNeuT ALPs – arXiv: 2202.12317 (re-cast)
- MicroBooNE ALPs – arXiv: 2202.03447 (re-cast)

K. Kelly, S. Kumar and Z. Liu Phys. Rev. D 103 (2021) 9, 095002
