Lorentz violation and non-standard interactions are two of the most popular scenarios beyond the Standard Model of particle physics. Both of these can affect neutrino oscillations significantly. However, their effects can mimic each other, and it would be difficult to distinguish between them in any fixed-baseline neutrino experiment. We show that atmospheric neutrinos, having access to a wide range of baselines, can break this degeneracy. Observations of core-passing atmospheric neutrinos and antineutrinos would be a potent tool to discriminate between these two new-physics scenarios.

Brief discussion on Lorentz Violation (LV)

Spontaneous Lorentz Symmetry Breaking

- Lorentz symmetry A key ingredient of the Standard Model (SM) & local Quantum field theories
- However, there are a few proposed models in string theory and loop quantum gravity which allow for Lorentz Invariance Violation (LIV)
- Direct observation of LIV at low energies would provide access to the Planck-scale (*Mp*) physics

CPT violation and the Standard Model, Colladay, Kostelecky, PRD 55 (1997) 6760 - 6774

Spontaneous Lorentz Symmetry Breaking

CPT violation and the Standard Model, Colladay, Kostelecky, PRD 55 (1997) 6760 - 6774

Spontaneous Lorentz Symmetry Breaking

$$\Rightarrow \mathcal{L}' \supseteq \frac{\lambda}{(M_p)^k} \langle T \rangle \,\overline{\psi} \,\Gamma \left(i\partial\right)^k \psi + h.c.,$$

For $k = 0$
 $\mathcal{L}' = \frac{1}{2} \left[a_\mu \overline{\psi} \gamma^\mu \psi + b_\mu \overline{\psi} \gamma_5 \gamma^\mu \psi \right] + h.c.$

Lorentz violation (LV) arises from the interaction of neutrinos with the spacetime itself. The LV can manifest itself in vacuum as well as in matter.

Note that the LIV parameters $(a^{\mu})_L$ or $(a^{\mu})_R$ break the CPT symmetry, since the elements of $(a^{\mu})_L$ or $(a^{\mu})_R$ change sign under the CPT transformation. Therefore, the LIV parameters $(a^{\mu})_L$ or $(a^{\mu})_R$ are known as CPT-violating LIV parameters.

In case of atmospheric neutrinos, $\mu - \tau$ channel is dominant, hence, we consider only $a_{\mu\tau}$ in our analysis (both positive and negative real values)

Effect of $a_{\mu\tau}$ on P ($\nu_{\mu} \rightarrow \nu_{\mu}$) channel

Effect of $a_{\mu\tau}$ on P ($\nu_{\mu} \rightarrow \nu_{\mu}$) channel

Brief discussion on Non-Standard Interactions (NSI)

Neutral-current Non-Standard Interactions (NSI) Neutral-current NSI in propagation through matter. $\mathcal{L}_{\text{NC-NSI}} = -2\sqrt{2}G_{F}\varepsilon_{\alpha\beta}^{Cf}(\bar{v}_{\alpha}\gamma^{\rho}P_{L}v_{\beta})(\bar{f}\gamma_{\rho}P_{C}f)$ where, $P_{I} = (1 - \gamma_{5})/2$, $P_{R} = (1 + \gamma_{5})/2$, and C = L, R. For neutral and isoscalar Earth $\varepsilon_{\alpha\beta} \approx \varepsilon_{\alpha\beta}^{e} + 3 \varepsilon_{\alpha\beta}^{u} + 3 \varepsilon_{\alpha\beta}^{d}$ $\varepsilon_{\alpha\beta} = \sum_{f=e,u,d} \frac{V_f}{V_{CC}} \left(\varepsilon_{\alpha\beta}^{Lf} + \varepsilon_{\alpha\beta}^{Rf} \right)$ $\mathcal{L}_{\text{eff}} = \mathcal{L}_{\text{SM}} + \frac{c^{d=5}}{\Lambda} \mathcal{O}^{d=5} + \frac{c^{d=6}}{\Lambda^2} \mathcal{O}^{d=6} + \cdots$ def Weinberg Operator: LLHH, A: New Physic d=5 Weinberg Operator: LLHH, Λ: New Physics Scale S. Weinberg, PRL 43 (1979) 1566 where, $V_{CC} = \sqrt{2}G_F N_e$, $V_f = \sqrt{2}G_F N_f$, f = e, u, d. NSI appears due to dimension six four fermion operators $H_{mat} = \sqrt{2}G_F N_e \begin{pmatrix} 1 + \varepsilon_{ee} & \varepsilon_{e\mu} & \varepsilon_{e\tau} \\ \varepsilon_{e\mu}^* & \varepsilon_{\mu\mu} & \varepsilon_{\mu\tau} \\ \varepsilon_{e\tau}^* & \varepsilon_{e\tau}^* & \varepsilon_{\tau\tau} \end{pmatrix}$ hermiticity of the interactions demands $\varepsilon^{f}_{\beta\alpha,C} = (\varepsilon^{f}_{\alpha\beta,C})^{*}$

In atmospheric neutrinos, $\mu - \tau$ channel is dominant, hence, we choose to constrain $\varepsilon_{\mu\tau}$ (only real values)

$$\mathcal{H}_{mat} = \sqrt{2}G_F N_e \begin{pmatrix} 1 & 0 & 0\\ 0 & 0 & \varepsilon_{\mu\tau}\\ 0 & \varepsilon_{\mu\tau}^* & 0 \end{pmatrix}$$

$$\mathring{A} = \sqrt{2}G_F N_e \mathcal{E}$$

If this condition gets satisfied,

then there is a degeneracy between "LV" and "NSI" parameters. This is also true for the case of antineutrino

$$\mathring{A} = \sqrt{2}G_F N_e \mathcal{E}$$

Such degeneracy is obvious for the current and future "fixed-baseline neutrino oscillation experiments",

where the line-averaged constant matter density approximation holds well.

Core-Passing Neutrinos: A unique tool to break this degeneracy between LV and NSI

P1 - P2 disfavours SM when " $a_{\mu\tau}$ " has non-zero values

Beyond P1-P2, SM gets disfavored at > 95% C.L.

P3-P4 constrains the hypothesis of non-zero values of " $\varepsilon_{\mu\tau}$ " at 95% C.L.

• The common major axis informs, the best-fit values of $\varepsilon_{\mu\tau}$ that can mimic the non-zero values of $a_{\mu\tau}$.

• P5 discards any values of $\varepsilon_{\mu\tau}$ including the mimicking value with $a_{\mu\tau} = 0.475$ $\times 10^{-23}$ GeV at $\geq 95\%$ C.L.

- The Core-passing atmospheric neutrinos and antineutrino can distinguish between the two popular beyond the Standard Model (BSM) scenarios, LV and NSI.
- The Charge Identification Capability (CID) of ICAL detector improves the power to discriminate between these two BSM scenarios.
- High-precision atmospheric neutrino data from currently running experiments like Super-K, IceCube, and ORCA and upcoming experiments like Hyper-K, DUNE, and P-ONE will certainly help to improve such discrimination.

$$\begin{split} H_{ij} &= E\delta_{ij} + \frac{m_{ij}^2}{2E} + \frac{1}{E} \left(\mathbf{a}_L^{\mu} p_{\mu} - c_L^{\mu\nu} p_{\mu} p_{\nu} \right)_{ij} \\ p &\equiv (E, -E\hat{p}) \\ i, j \to \text{flavour indices} \\ \mu, \nu \to \text{space time indices} \\ m_{ij}^2 \to \text{mass squared splitting in flavour indices} \end{split}$$

In our work, we only focus on CPT-violating LIV parameters $(a^{\mu})_{ij}$ where μ is the spacetime index and i, j are flavor indices. The couplings of $(a^{\mu})_{ij}$ with neutrinos are flavor-dependent.

Remember, here, we consider a scenario in which the Lorentz symmetry is broken spontaneously, giving nonzero vev to a 4-vector $(a^{\mu})_{ij}$. Here $(a^{\mu})_{ij}$ combines the information on the vev and couplings of a^{μ} with neutrinos.

We work in an approximately inertial frame and consider only the timelike (isotropic) component of the LIV parameters to be nonzero ($a^0 \neq 0$ and $p^0 = E$).

The Sun-centered celestial-equatorial (SCCE) frame can be taken to be such a frame when the small effects due to gravity and boost due to the Earth's motion are ignored.

Oscillation Dip in presence of LIV

Oscillation Dip in presence of NSI

Identifying LIV through the Shift in oscillation Dip Location

The statistical fluctuations shown by shaded boxes are the root-mean-square deviation of 100 independent distributions of U/D ratio, each for 10 years, whereas the mean of these distributions are shown by solid lines. Even after detector smearing and statistical fluctuations, the oscillation dip is visible in ICAL and shift in oscillation dip location may hint towards LIV. Note that the shift occurs in the opposite direction for neutrinos and antineutrinos for a given LIV parameter. Also, the dip is deeper for antineutrino as compared to neutrino due less inelasticity in antineutrino events

Identifying NSI through the Shift in oscillation Dip Location

The statistical fluctuations shown by shaded boxes are the root-mean-square deviation of 100 independent distributions of U/D ratio, each for 10 years, whereas the mean of these distributions are shown by solid lines. Even after detector smearing and statistical fluctuations, the oscillation dip is visible in ICAL and shift in oscillation dip location may hint towards LIV. Note that the shift occurs in the opposite direction for neutrinos and antineutrinos for a given NSI parameter. Also, the dip is deeper for antineutrino as compared to neutrino due less inelasticity in antineutrino events
