

Assessing MAGIS capabilities to measure the properties of GW signals from compact binaries

210X.XXXXX w/ Zach Bogorad & Peter W Graham

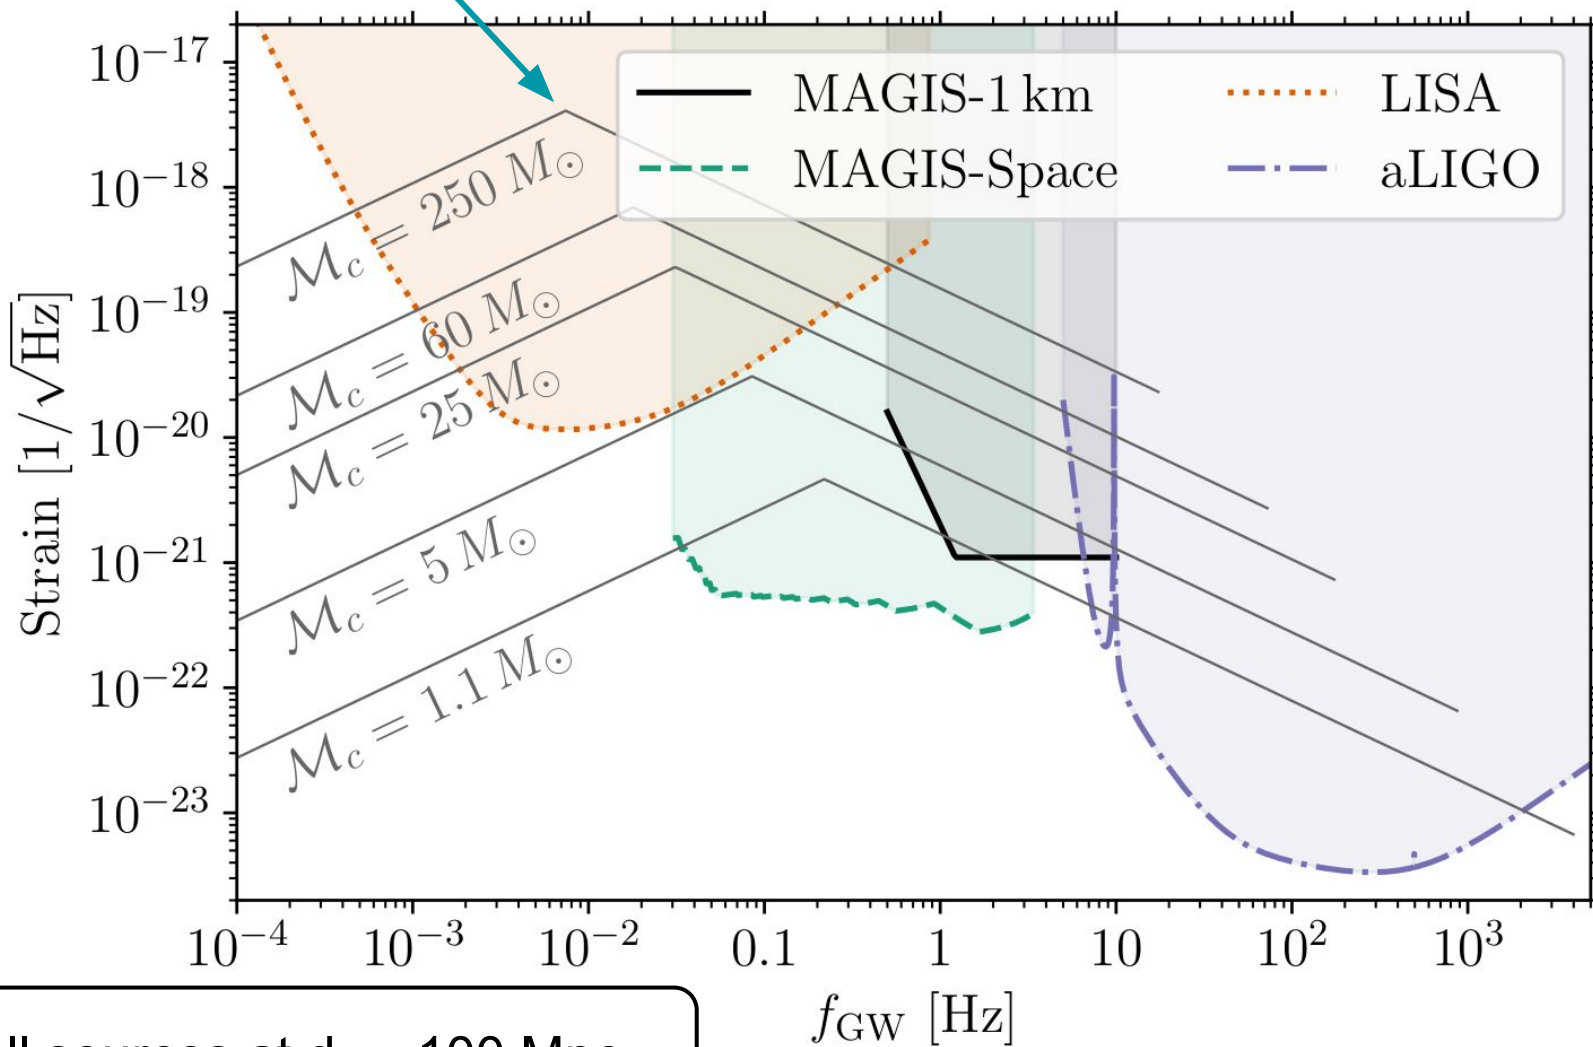

Sebastian Baum

Stanford University

1 yr before merger

All sources at $d_L = 100$ Mpc

What is special about AI GW detectors?

- Single baseline
 - ⇒ different antenna functions
- Two timescales (atom free-fall time, laser travel time)
 - ⇒ different shape of the sensitivity curve
- Terrestrial or mid-Earth orbit
 - ⇒ detector re-orientation on hour-timescales
- Small ratio of GW frequency⁻¹/GW wavelength to effective “baseline”
 - ⇒ excellent sky localization of sources

Quick reminder of sky-localization capabilities

Three options:

- High signal-to-noise ratio measurement of the waveform in many spatial directions (very hard)
- Time-of-flight between multiple detectors
- Accelerated motion of detector wrt the GW source

Quick reminder of sky-localization capabilities

Three options:

- High signal-to-noise ratio measurement of the waveform in many spatial directions (very hard)
- Time-of-flight between multiple detectors
- Accelerated motion of detector wrt the GW source

Ultimately, these both lead to the diffraction limit:

$$\sigma_{\sqrt{\Omega}} \propto \lambda_{\text{GW}} / L_{\text{baseline}}$$

Quick reminder of sky-localization capabilities

Three options:

- High signal-to-noise ratio measurement of the waveform in many spatial directions (very hard)
- Time-of-flight between multiple detectors
- Accelerated motion of detector wrt the GW source

Ultimately, these both lead to the diffraction limit:

$$\sigma_{\sqrt{\Omega}} \propto \lambda_{\text{GW}} / L_{\text{baseline}}$$

$$\sigma_{\Omega}^{\text{LIGO}} \sim 10^{\circ} \left(\frac{1 \text{ kHz}}{f_{\text{GW}}} \right) ; \quad \sigma_{\Omega}^{\text{AI}} \sim 0.3^{\circ} \left(\frac{1 \text{ Hz}}{f_{\text{GW}}} \right) ; \quad \sigma_{\Omega}^{\text{LISA}} \sim 30^{\circ} \left(\frac{10 \text{ mHz}}{f_{\text{GW}}} \right)$$

Leading-order inspiral waveforms (pol. basis)

- Frequency evolution (“chirp”) $\frac{df_{\text{GW}}}{dt} = \frac{96}{5} \pi^{8/3} \mathcal{M}_c f_{\text{GW}}^{11/3}$

with the (detector frame) “chirp mass” $\mathcal{M}_c = \frac{(m_1 m_2)^{3/5}}{(m_1 + m_2)^{1/5}}$

- Polarization basis waveforms: $\underline{\underline{h}}(t) = h_+(t) \underline{\underline{e}}_+ + h_\times(t) \underline{\underline{e}}_\times$

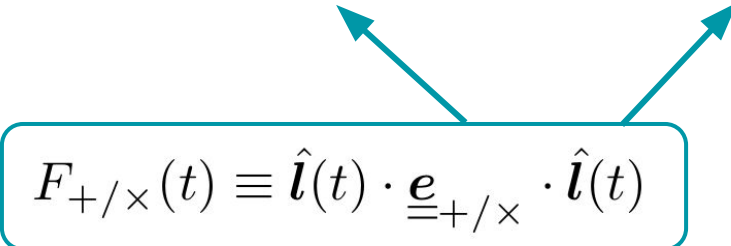

$$h_{+/\times}(t) = \frac{2\mathcal{M}_c^{5/3} [\pi f_{\text{GW}}(t)]^{2/3}}{d_L} \begin{cases} \left[1 + (\hat{\mathbf{L}} \cdot \hat{\mathbf{n}})^2 \right] \cos \Phi_{\text{GW}}(t) \\ 2 (\hat{\mathbf{L}} \cdot \hat{\mathbf{n}}) \sin \Phi_{\text{GW}}'(t) \end{cases}$$

$$\cos \iota \equiv \hat{\mathbf{L}} \cdot \hat{\mathbf{n}}$$

Leading-order inspiral waveforms (antenna func.)

- The response of a single-baseline detector is then

$$h(t) = \hat{\mathbf{l}}(t) \underline{\underline{\mathbf{h}}}(t) \hat{\mathbf{l}}(t) = F_{+}(t) h_{+}(t) + F_{\times}(t) h_{\times}(t)$$

$$F_{+/\times}(t) \equiv \hat{\mathbf{l}}(t) \cdot \underline{\underline{\mathbf{e}}}_{+/\times} \cdot \hat{\mathbf{l}}(t)$$

Parameters describing the binary

	Parameter	Benchmark value
Chirp Mass	$\mathcal{M}_c = (m_1 m_2)^{3/5} / (m_1 + m_2)^{1/5}$	
Mass ratio	$q = m_1 / m_2$	1.15
Luminosity distance	d_L	
Binary phase at $f_{\text{GW}}^{\text{ref}}$	Φ_0	0
Time of merger	t_c	solar equinox
Inclination angle	ι	45°
Polarization angle	ψ	60°
Right ascension	α	60°
Declination	δ	6.6° (30° above ecliptic)

Overview of the code

Fisher-matrix approach to forecast parameter reconstruction

- Computationally “cheap”
- Only reliable in high signal-to-noise ratio limit

Fisher-matrix approach

- The detector records a time-domain signal: $h(t)$

Fisher-matrix approach

- The detector records a time-domain signal: $h(t)$
- Fourier-transform into the frequency domain,

$$\tilde{h}(f) = \int_{-\infty}^{\infty} dt e^{2\pi i f t} h(t)$$

Fisher-matrix approach

- The detector records a time-domain signal: $h(t)$
- Fourier-transform into the frequency domain,

$$\tilde{h}(f) = \int_{-\infty}^{\infty} dt e^{2\pi i f t} h(t)$$

- Define the inner product: $\langle h, g \rangle = 4 \operatorname{Re} \left[\int_0^{\infty} df \frac{\tilde{h}^*(f) \tilde{g}(f)}{S_n(f)} \right]$

one-sided detector noise PSD

Fisher-matrix approach

- The detector records a time-domain signal: $h(t)$
- Fourier-transform into the frequency domain,

$$\tilde{h}(f) = \int_{-\infty}^{\infty} dt e^{2\pi i f t} h(t)$$

- Define the inner product: $\langle h, g \rangle = 4 \operatorname{Re} \left[\int_0^{\infty} df \frac{\tilde{h}^*(f) \tilde{g}(f)}{S_n(f)} \right]$

- Signal-to-noise ratio $\rho^2 = \langle h, h \rangle$

and Fisher information matrix $\Gamma_{ij} = \left\langle \frac{\partial h}{\partial \theta_i}, \frac{\partial h}{\partial \theta_j} \right\rangle$

Overview of the code

Fisher-matrix approach to forecast parameter reconstruction

- Computationally “cheap”
- Only reliable in high signal-to-noise ratio limit $C_{ij} = \Gamma_{ij}^{-1}$

Overview of the code

Fisher-matrix approach to forecast parameter reconstruction

- Computationally “cheap”
- Only reliable in high signal-to-noise ratio limit $C_{ij} = \Gamma_{ij}^{-1}$
 - Calculate (3.5/3.0 PN) waveforms in time-domain (good for accelerated det., but computationally expensive)
 - FFT to frequency domain (requires choosing window functions... current implementation uses Planck window)
 - Some subtleties due to the accelerated detector frame (what do we mean by “detector frame” masses? What is the clock? ...)
 - Include priors on periodic parameters $(\alpha, \delta, \iota, \psi)$

Detector benchmarks

- (Network of) terrestrial MAGIS-1 km detectors

Detector benchmarks

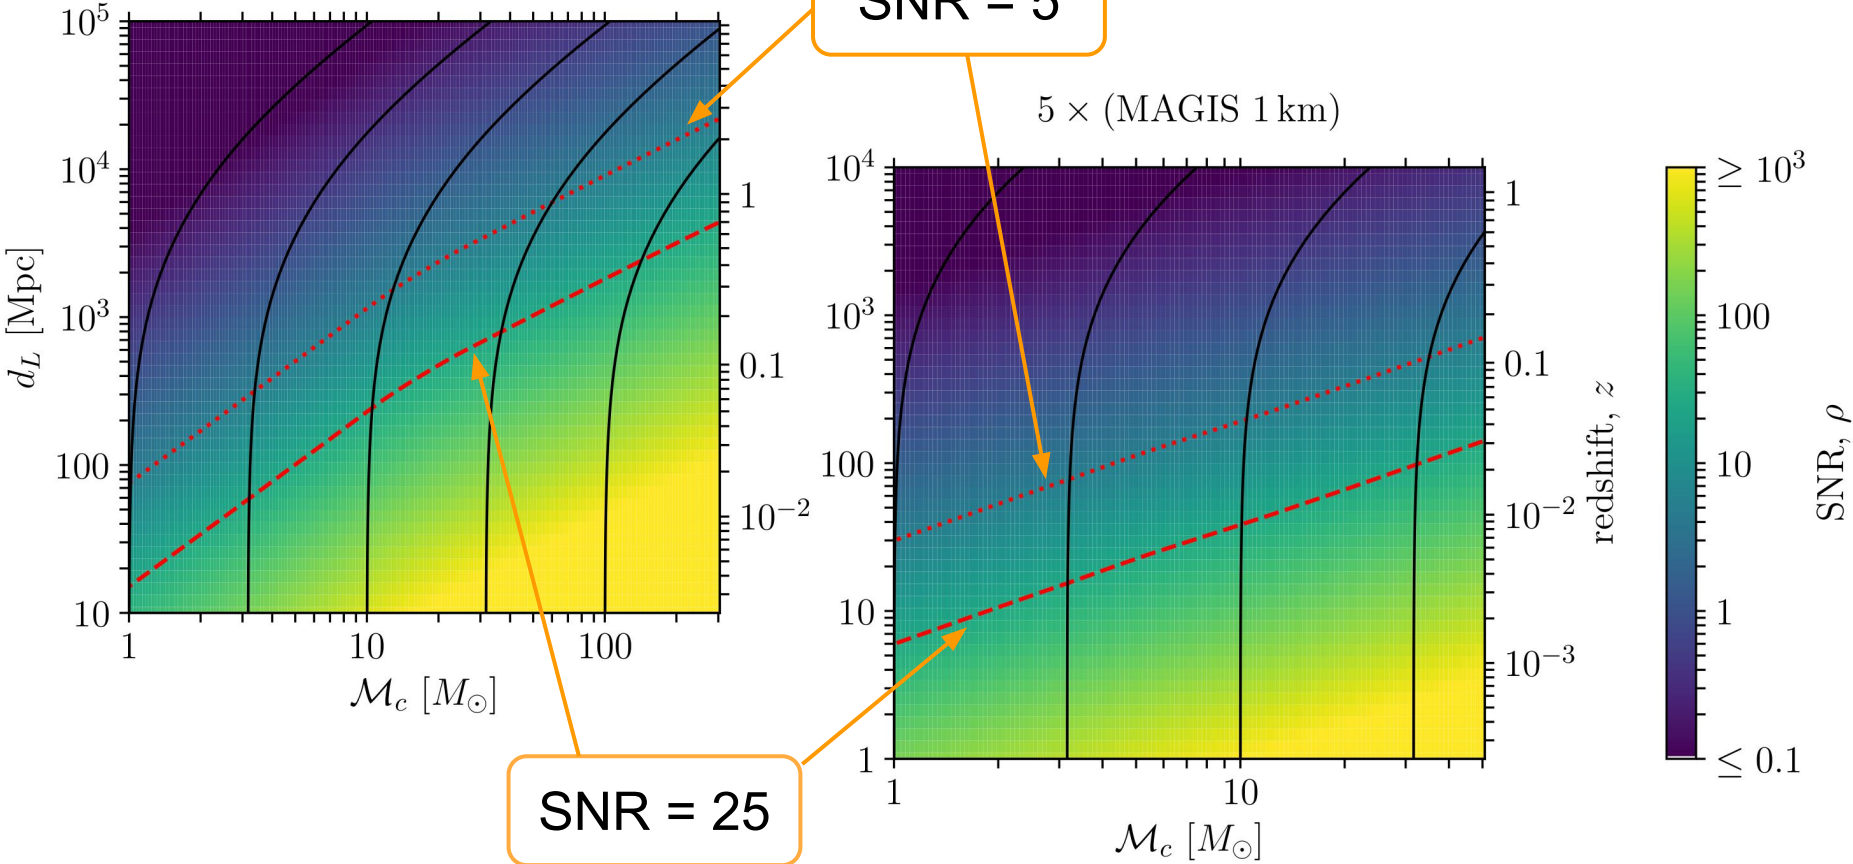

- (Network of) terrestrial MAGIS-1 km detectors

- MAGIS-space in mid-Earth orbit
 - 20,000 km radius / 7.8 h period orbit
 - 3,600 km separation between the satellites
 - Consider orbits inclined $\{0^\circ, 45^\circ, 90^\circ\}$ to ecliptic
 - For comparison, study also heliocentric orbits at $\{0.5, 1, 2\}$ AU

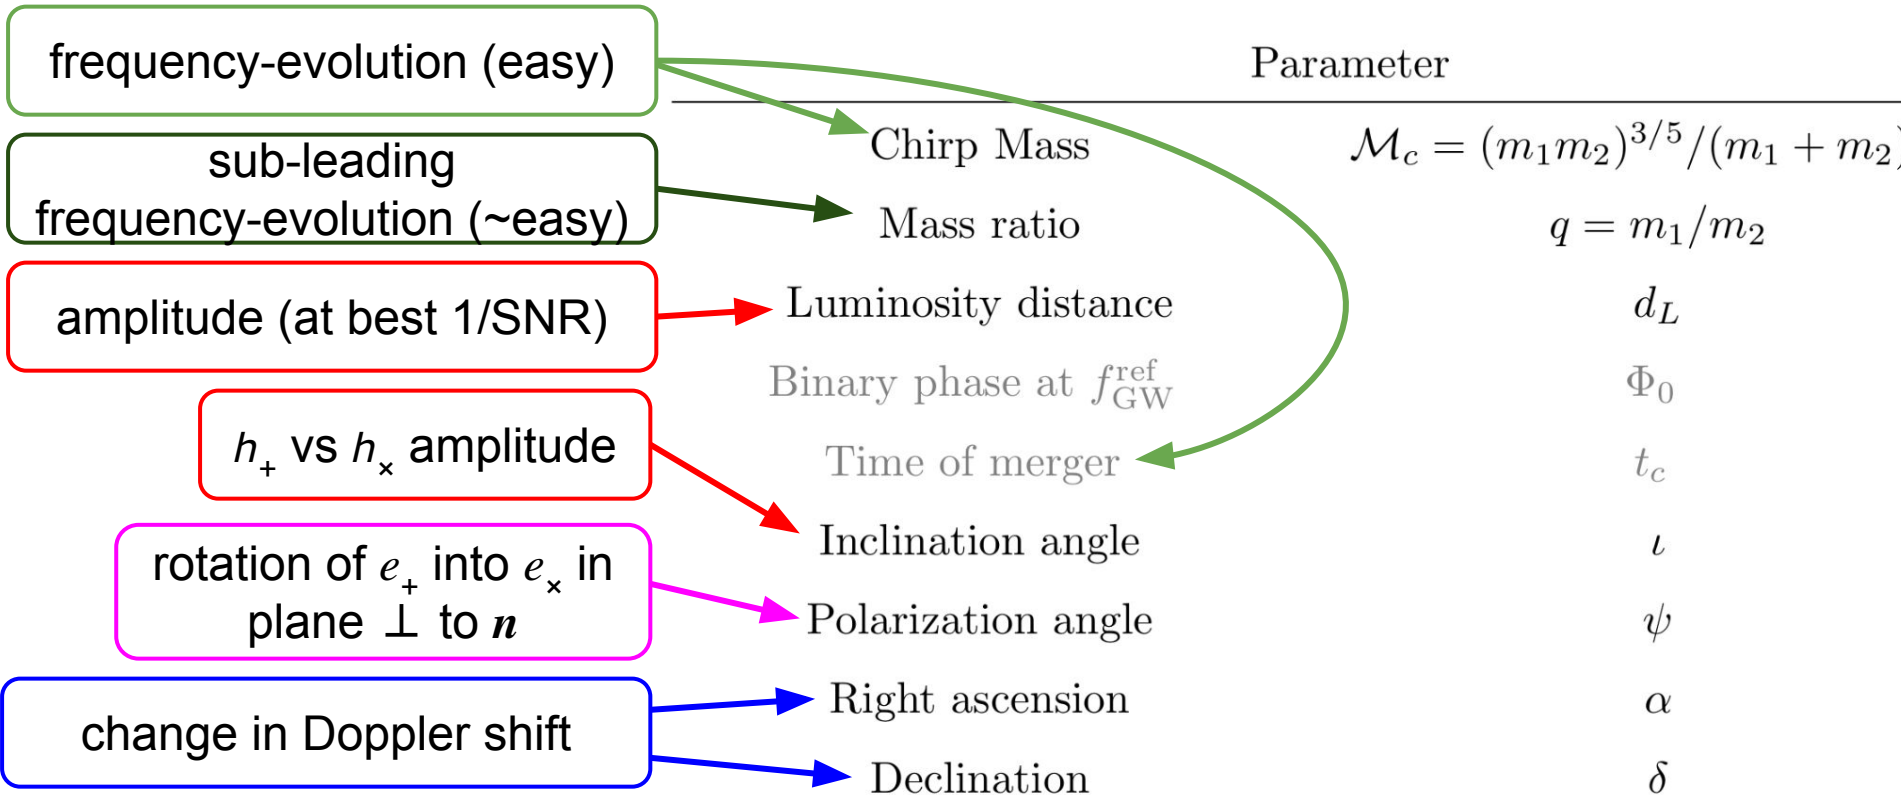

Results: SNR in $\mathcal{M}_c - d_L$ plane

MAGIS-space, $\delta_{\text{det}} = -23^\circ$

Note different ranges of axes

Heuristics of parameter reconstruction

Results: $\sigma(d_L)$ in $\mathcal{M}_c - d_L$ plane

MAGIS-space, $\delta_{\text{det}} = -23^\circ$

Summary and comments

- Flexible code allows one to explore the capabilities of MAGIS to reconstruct the parameters of GW signals, i.e. to better understand the science case of MAGIS
- Evaluate possible sites for terrestrial MAGIS / different orbits for MAGIS-space
- The mid-band offers unique possibilities for the sky-localization of GW sources
 - Allows for an early warning system for electromagnetic follow-up!
- The mid-band is quite poor at measuring the luminosity distance
 - Combine with terrestrial laser-interferometers?

ICRS: Heliocentric equatorial coordinate system
