

Over-constraint Problem

Liban Warsame for the MaCh3 Group

MaQE Posterior

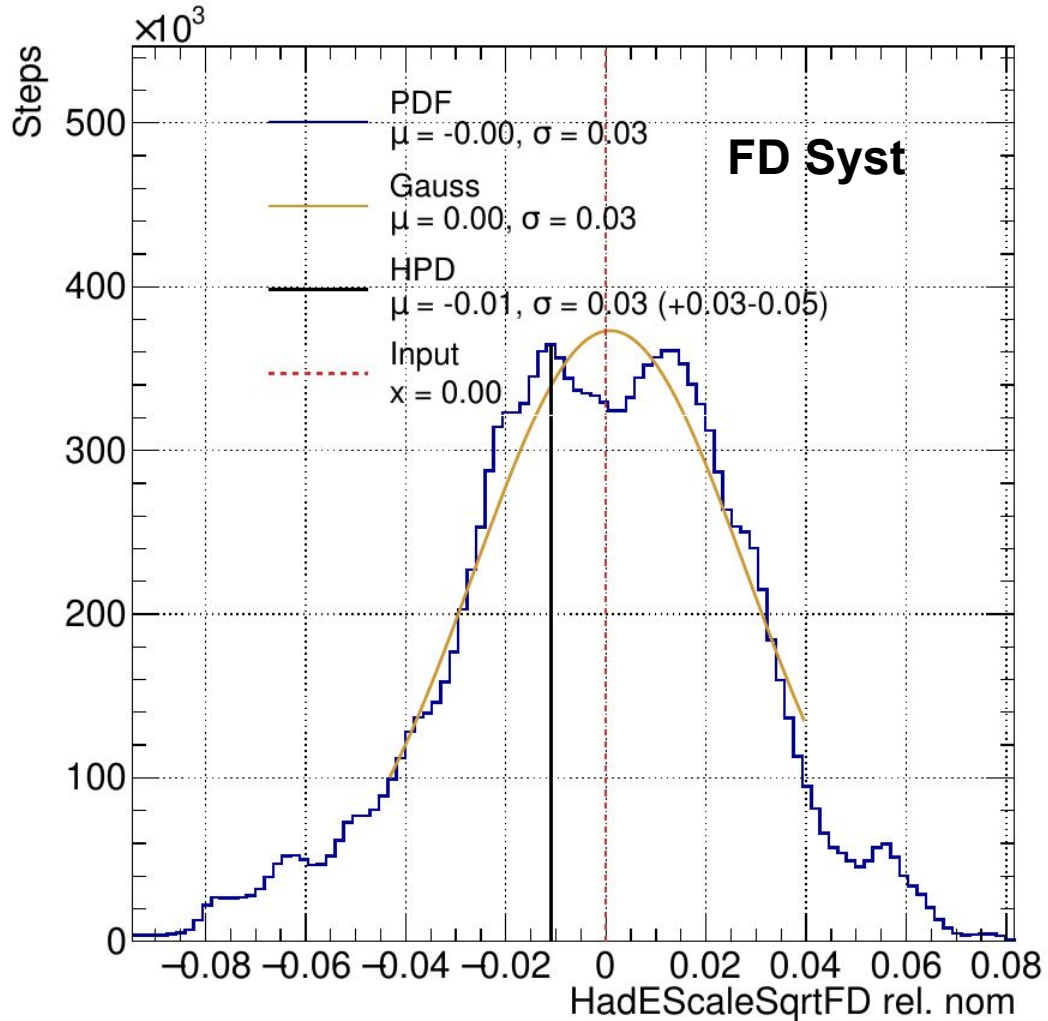

prefit $\sigma = 1$

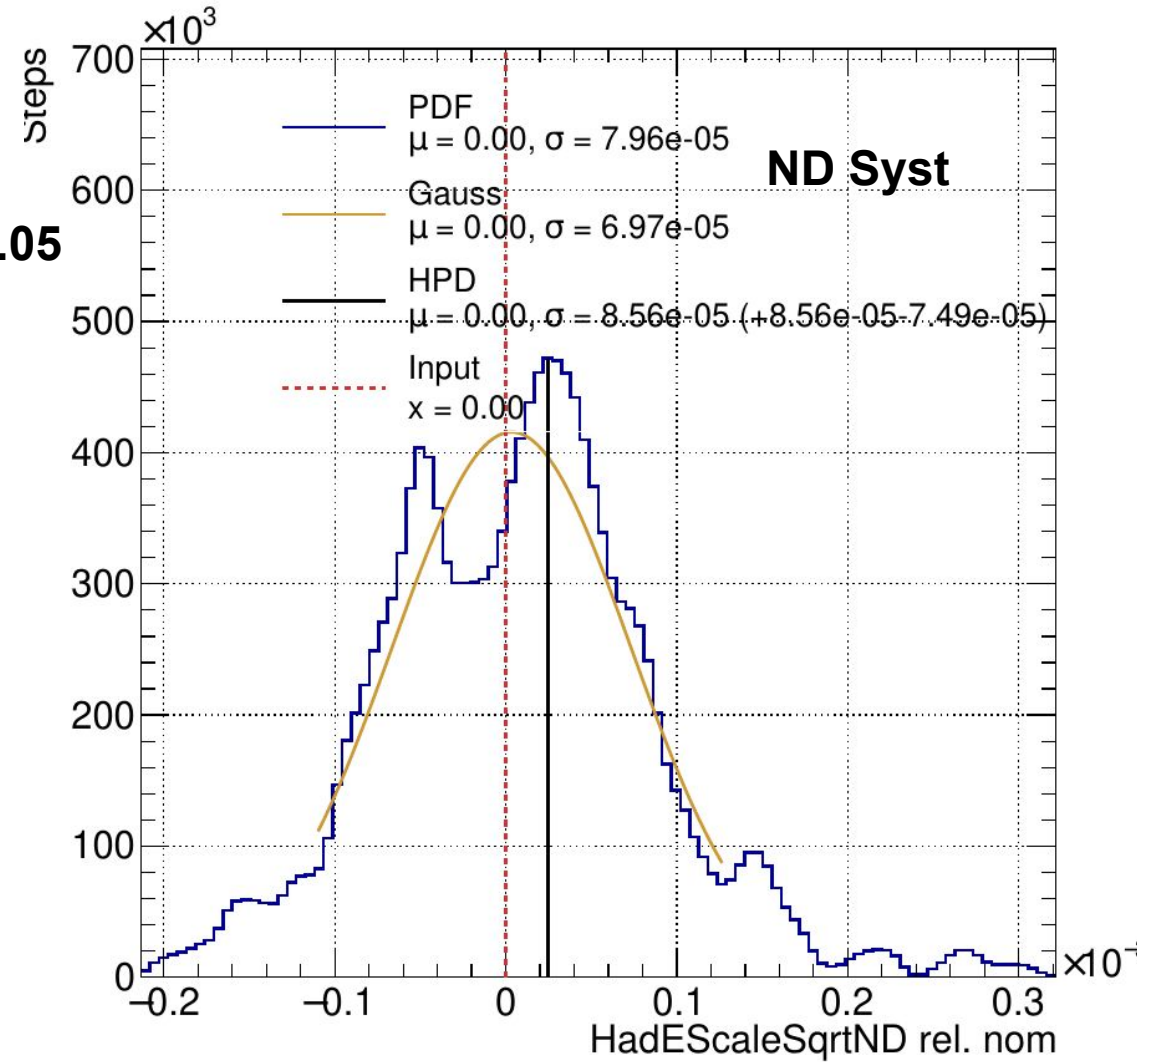

- Posterior/Prior ~ 0.0001 upon addition of ND samples
- Irregular shape due to bad-mixing

Detector Systematic Posterior

prefit $\sigma = 0.05$

Thoughts/Plans

- TDR analysis fixed issue by creating covariance matrix from ND detector systematics
 - We could try something similar
 - How did this have an effect on constraint on MaQE?
- Tried fitting to asimov data + poisson throw in each bin
 - Basically did nothing - stat error is far too small
 - Converged to higher LogL but posteriors widths are unchanged
- New idea - don't fix it...
 - Perform fits which show where model is lacking
 - **Add duplicate MaQE systematic at ND only**
 - Show degeneracy at ND is necessary.
