The search for CLFV with the Mu2e Experiment

Kevin Lynch, AD/BD/TSD and Mu2e

FNAL Summer 2024 Lecture Series

13 June 2024

What we'll cover…

- Let's start at the beginning
- What is CLFV?
- What is Mu2e and how does it work?
- Summary

What exactly to physicists think we already now?

- Example: Gravity, or Why Things Fall

What exactly to physicists think we already now?

How do we think about potential *high energy physics** experiments?

Mu2e lives here!

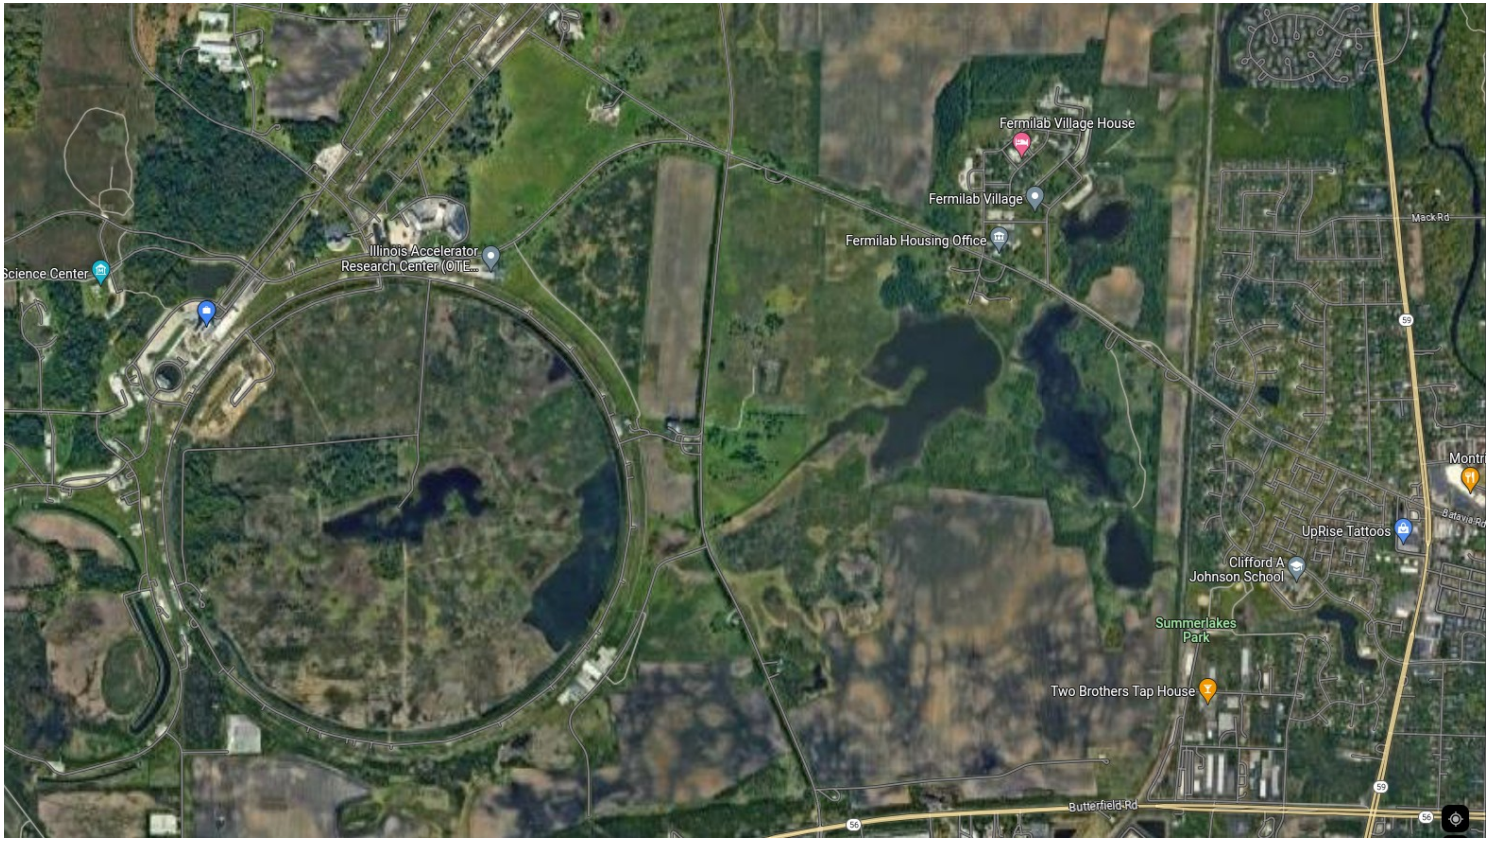
* There are also lots of non-HEP experiments you could do!

Intensity Frontier experiments are further split into two classes

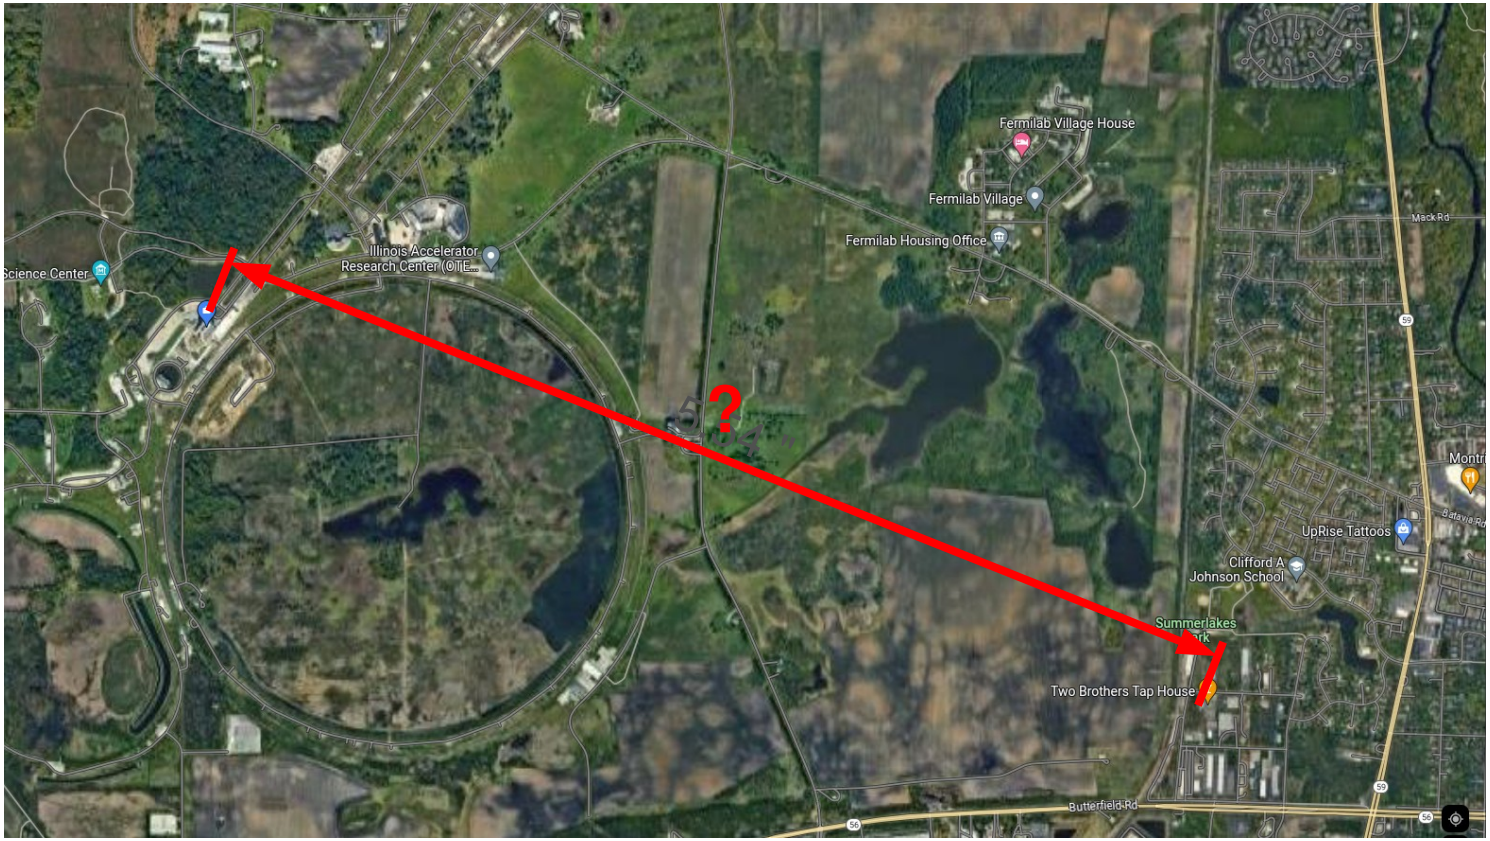
- Precision Measurements
  - Try to measure specific parameters with ridiculously high precision
    - Eg: Muon g-2
- Rare and Forbidden Process Searches
  - We look in huge piles of data for
    - Events the Standard Model predicts are extremely rare, in the hopes they occur more/less often, or
    - Events the Standard Model predicts don't happen at all, in the hopes that they occur more often than that
    - Eg: Mu2e

Precision Measurements: How far to Two Brothers?

Precision Measurements: How far to Two Brothers?



Precision Measurements: How far to Two Brothers?



Rare Searches: what is the natural frequency of people with blue hair?

Rare Searches: what is the natural frequency of people with blue hair?

Rare Searches: what is the natural frequency of people with blue hair?

Oh, and, make sure you aren't fooled by people who *dye* their hair blue … and then lie about it!

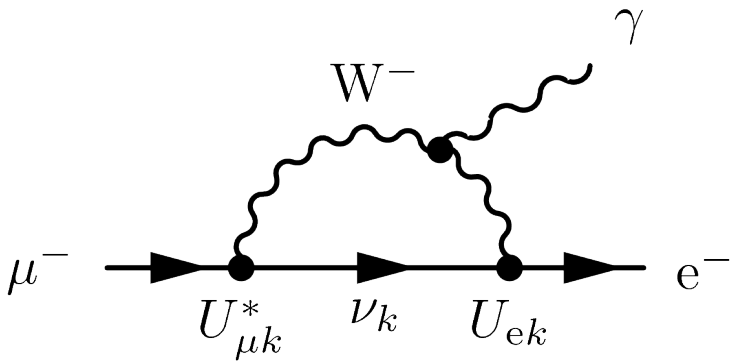
Mu2e (and our competitor COMET) are searches for charged lepton flavor violation with discovery potential

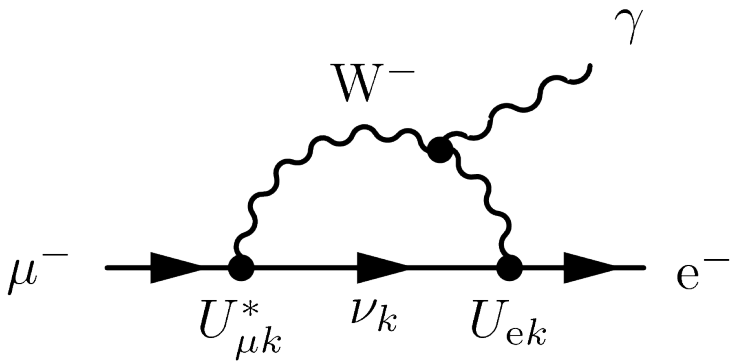
Mu2e (and our competitor COMET) are searches for charged lepton flavor violation with discovery potential

Although it has never been observed, we know that CLFV **must** occur, *even in the Standard Model*, through neutrino loop effects.



Mu2e (and our competitor COMET) are searches for charged lepton flavor violation with discovery potential

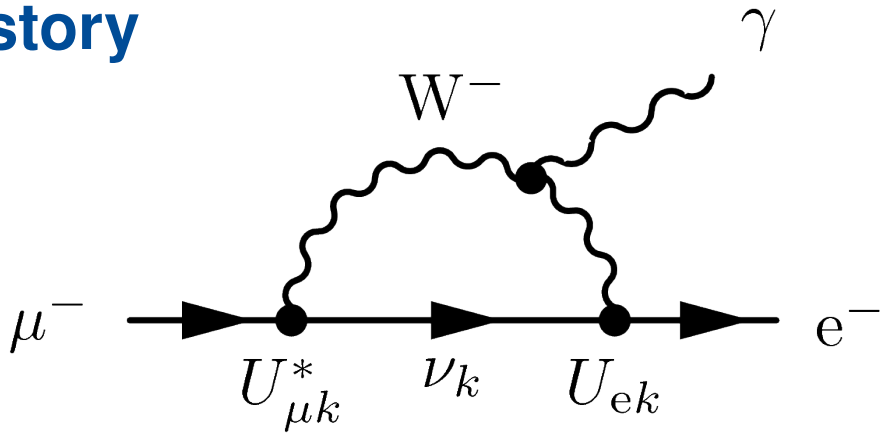
Although it has never been observed, we know that CLFV **must** occur, *even in the Standard Model*, through neutrino loop effects.



However, the predicted SM rates are unobservably small:

$$\mathrm{Br}(\mu \to e\gamma) = \frac{3\alpha}{32\pi} \left| \sum_{k=2,3} U^*_{\mu k} U_{ek} \frac{\Delta m^2_{1k}}{M^2_W} \right|^2 < 10^{-54}$$

This is a good news/bad news story



This is a good news/bad news story

Now, the good news: we'll never observe this!

Any signal of CLFV is unambiguous evidence for physics beyond the Standard Model!

There are many potential signatures of CLFV physics in the muon sector

Surface muon beams

$$\mu^+ \to \mathrm{e}^+\gamma$$

$$\mu^+ \to \mathrm{e}^+\mathrm{e}^+\mathrm{e}^-$$

$$\mu^+ e^- \leftrightarrow \mu^- e^+$$

Double CLFV!

"High" energy beams

$$\mu^- A(Z,N) \to \mathrm{e}^- A(Z,N)$$

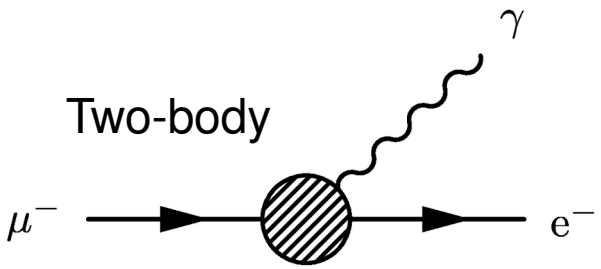
$$\mu^- A(Z,N) \to \mathrm{e}^+ A(Z-2,N)$$

CLFV and LNV!

There are a large number of experiments proposed to further address these channels; I apologize for only mentioning those I'm involved with.

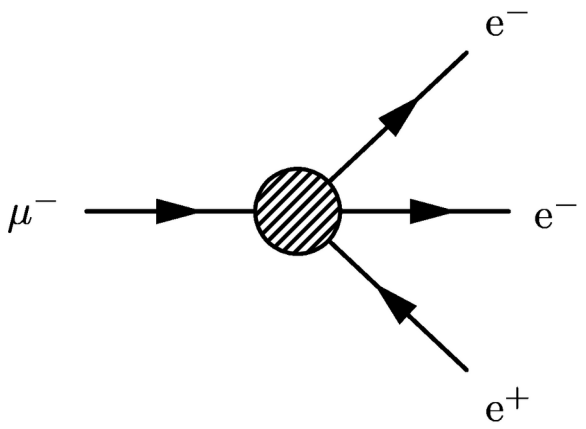
The most powerful signatures are being actively pursued

$\mu^+ \to e^+\gamma$



MEG/MEG-II at PSI

$\mu^+ \to e^+e^+e^-$



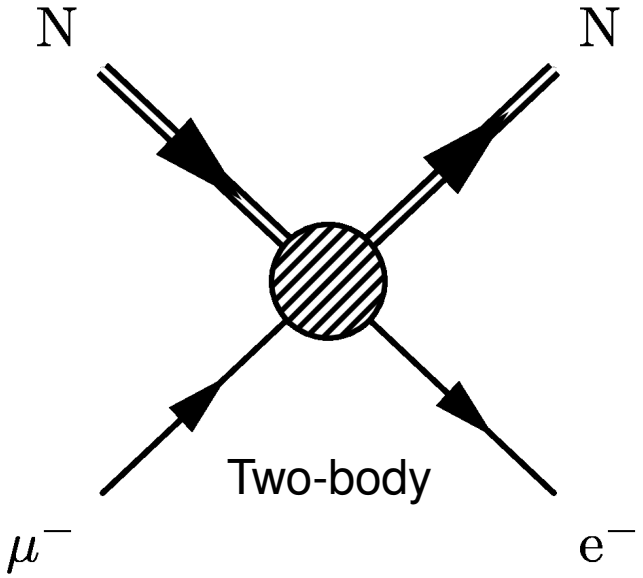
Mu3e at PSI

Coherent neutrinoless conversion is the Mu2e program

Mu2e and COMET will search for Coherent Conversion

$$\mu^- A(Z,N) \rightarrow \mathrm{e}^- A(Z,N)$$

$$R_{\mu \mathrm{e}} = \frac{\Gamma\left(\mu^- A \rightarrow e^- A\right)}{\Gamma\left(\mu^- A \rightarrow \nu_\mu A'\right)}$$



We're extending a long line of experiments designed to understand the mystery of muon flavor

Reminder that these cartoons hide a wealth of complex and interesting science and engineering

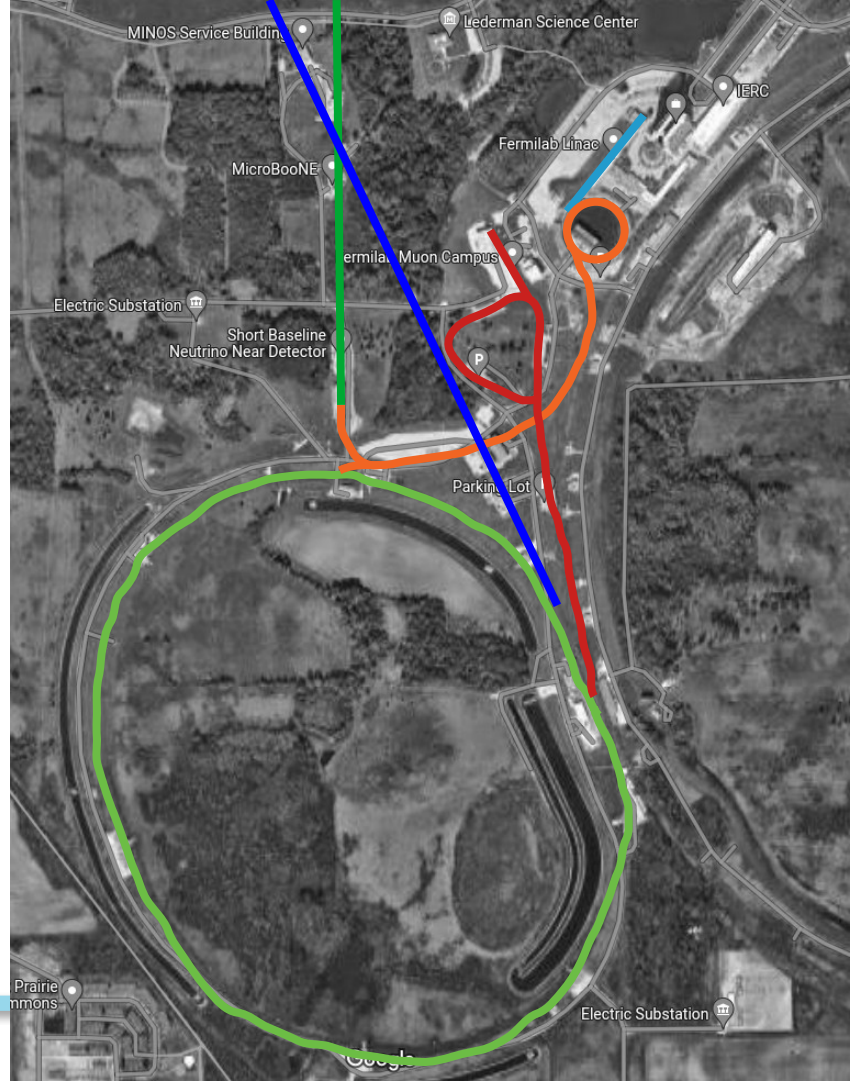
They also hide a vast hierarchy of scales!

They also hide a vast hierarchy of scales!

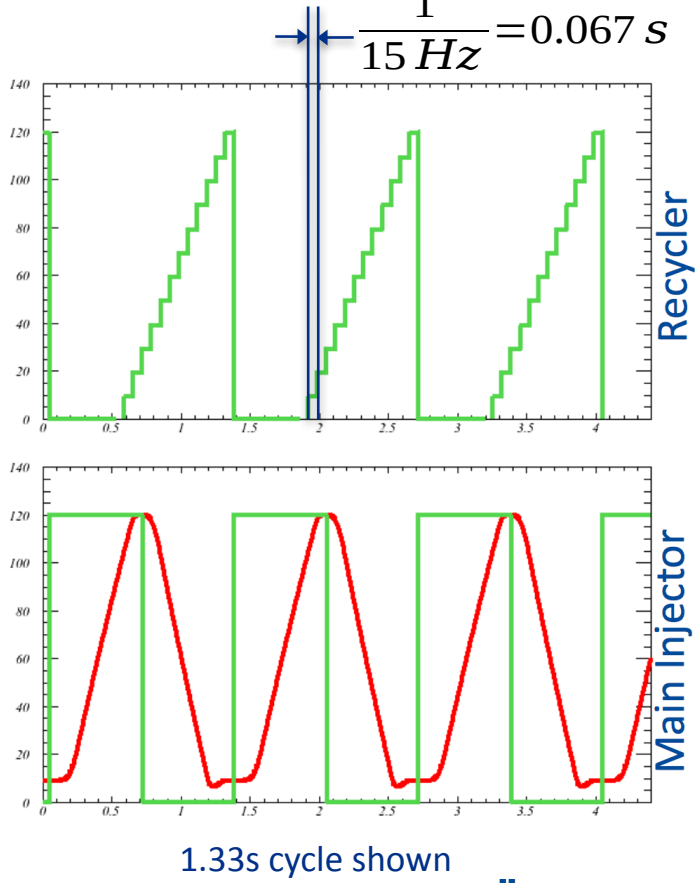
They also hide a vast hierarchy of scales!

- Linac (400MeV)
- Booster (8GeV)
- RR/MI (8GeV/120GeV)
- Muon Campus (3.094GeV/8GeV)
- BNB (8GeV)
- NuMI (120GeV)



The accelerator timeline is organized around the NuMI program

- H^- linac (1970, 1993, 2012)
  - 400 MeV linac ~20mA
- Booster synchrotron (1970)
  - H^- stripping injection (1978)
    - 16 turns to ~4.7x10^{12} p per pulse
  - Resonant Ramp from 0.4 to 8 GeV at 15 Hz
- Recycler (1998)
  - 3.3 km permanent magnet 8 GeV ring
  - Slip-stacking 12 Booster batches, ~56x10^{12} p
  - Also re-bunches beam for Muon Campus
- Main Injector (1998, but!)
  - 8 to 120 GeV ramp, cycle time 1.133*-1.4 s

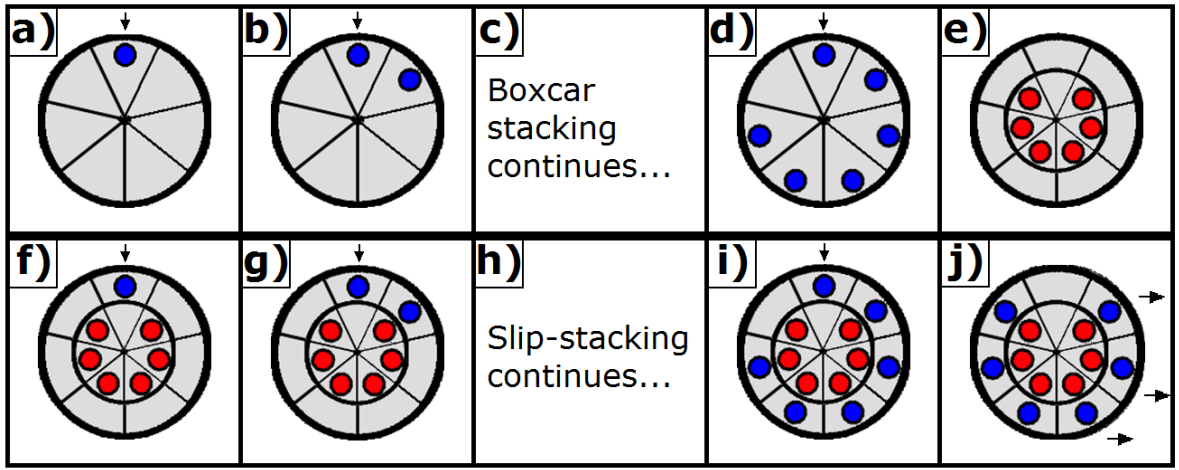


* 1.067s has been demonstrated recently!

Stacking beam in the Recycler is the key timeline constraint

- Slip stacking is a method of injecting multiple beams at different momenta into the same circular machine.
  - We combine slip stacking with boxcar stacking to stuff beam into the Recycler

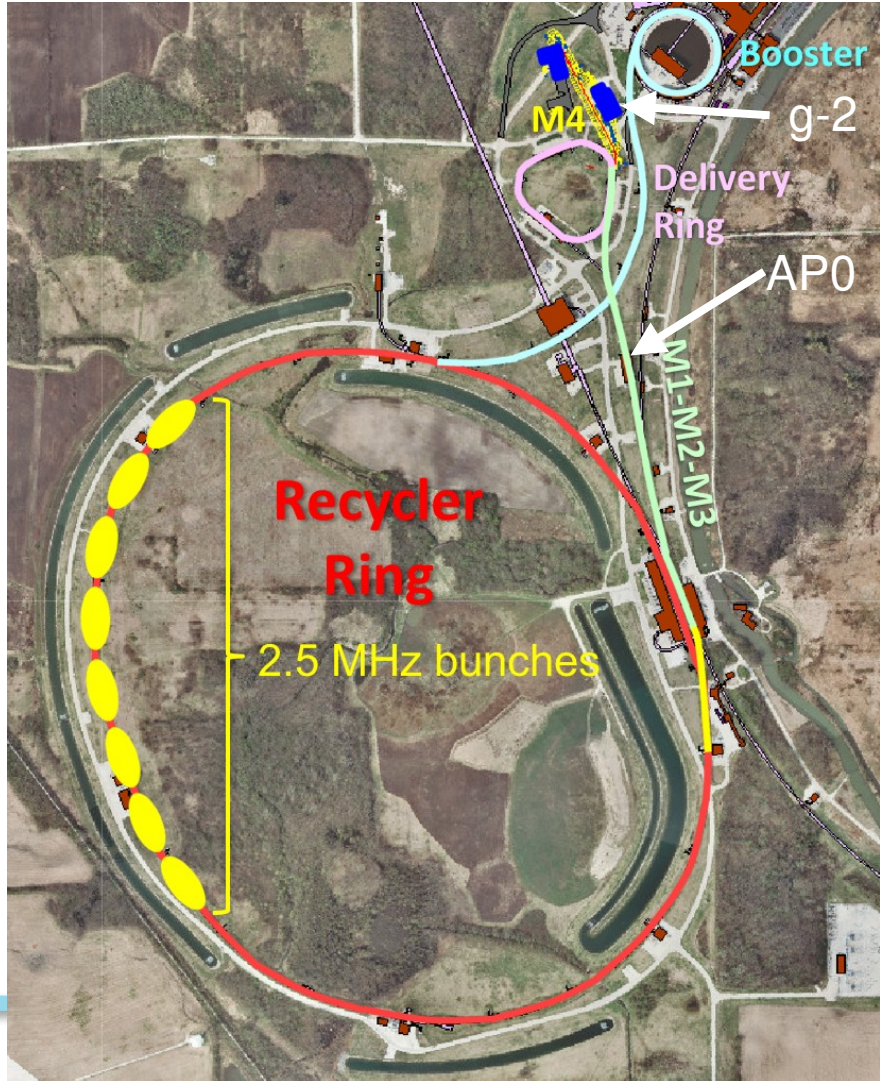
7x as many 53MHz RF buckets in RR/MI as in Booster (588/84) … 81 filled buckets per transfer



- These manipulations require 13 ticks of the Booster clock
  - 12 for injection, one for extraction

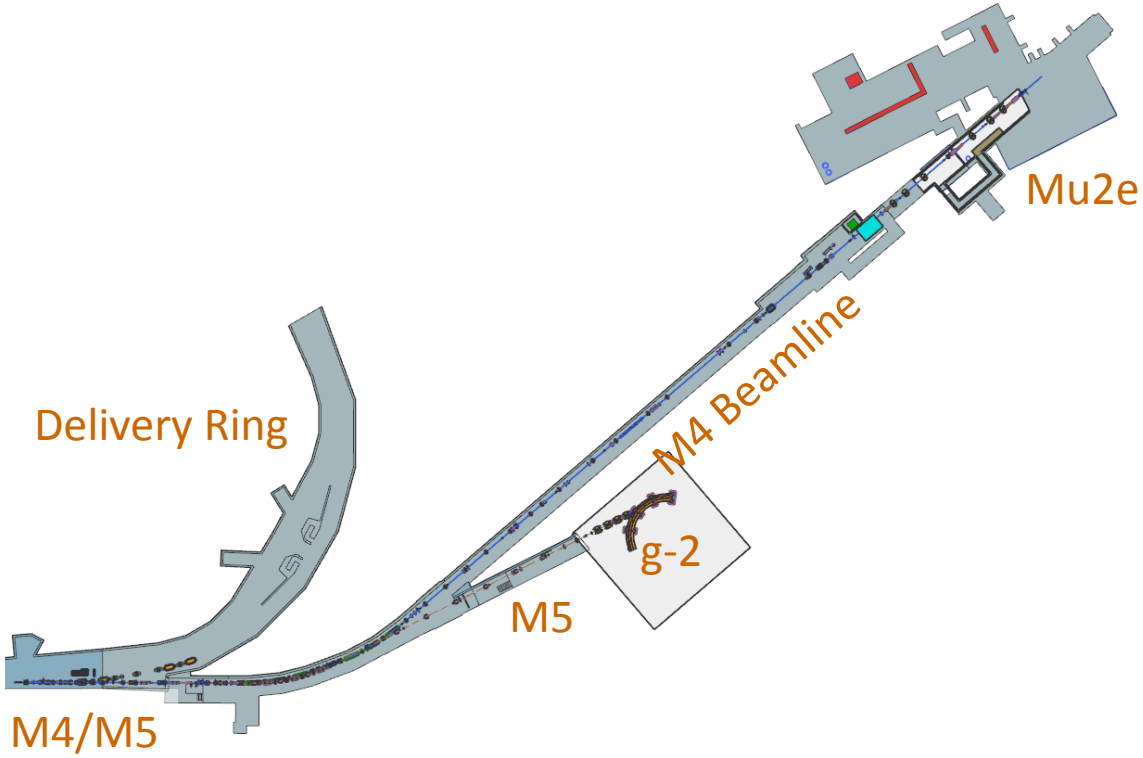
We want to take those spare protons and move them to Mu2e

- Each Booster batch is rebunched from 81 x 53MHz to 4 x 2.5MHz
- The rebunched beam pulses are extracted one at a time from the RR
- These pulses are injected into the 2.36MHz DR
- Those protons are then slow extracted to the experiment



We want to take those spare protons and move them to Mu2e

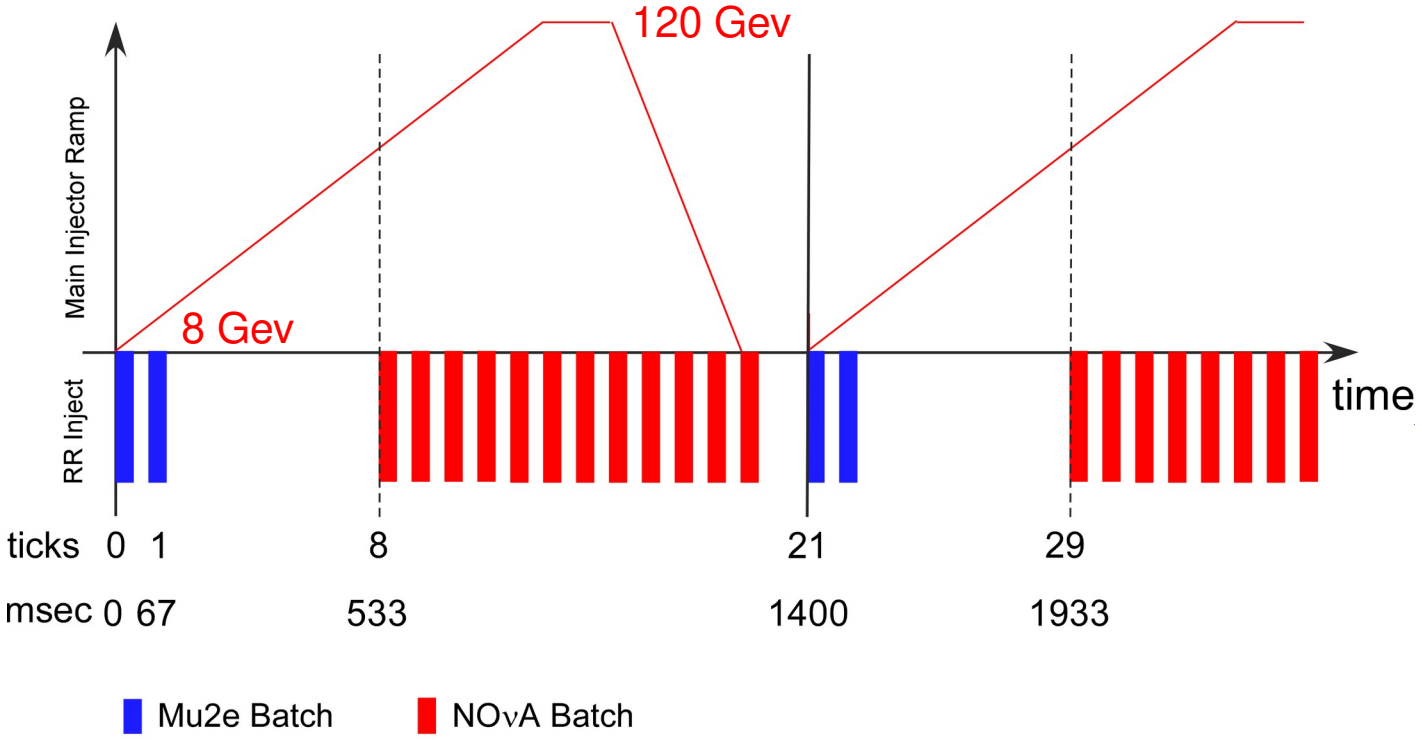
- Each Booster batch is rebunched from 81 x 53MHz to 4 x 2.5MHz
- The rebunched beam pulses are extracted one at a time from the RR
- These pulses are injected into the 2.36MHz DR
- Those protons are then slow extracted to the experiment



We want to take those spare protons and move them to Mu2e

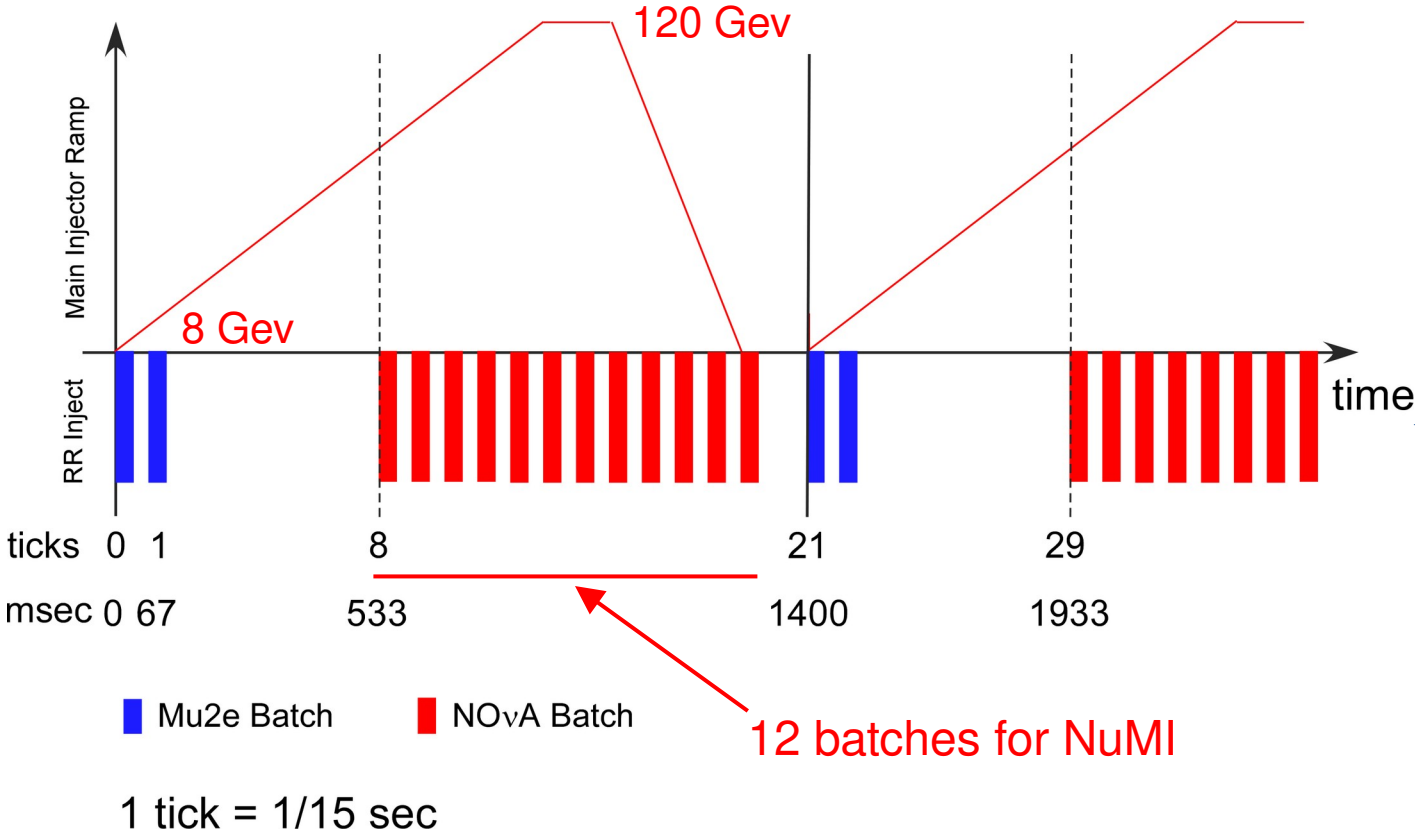
- Each Booster batch is rebunched from 81 x 53MHz to 4 x 2.5MHz
- The rebunched beam pulses are extracted one at a time from the RR
- These pulses are injected into the 2.36MHz DR
- Those protons are then slow extracted to the experiment

All our machine timelines are built around moving 12 successive Booster batches to the MI – how does this impact muons?

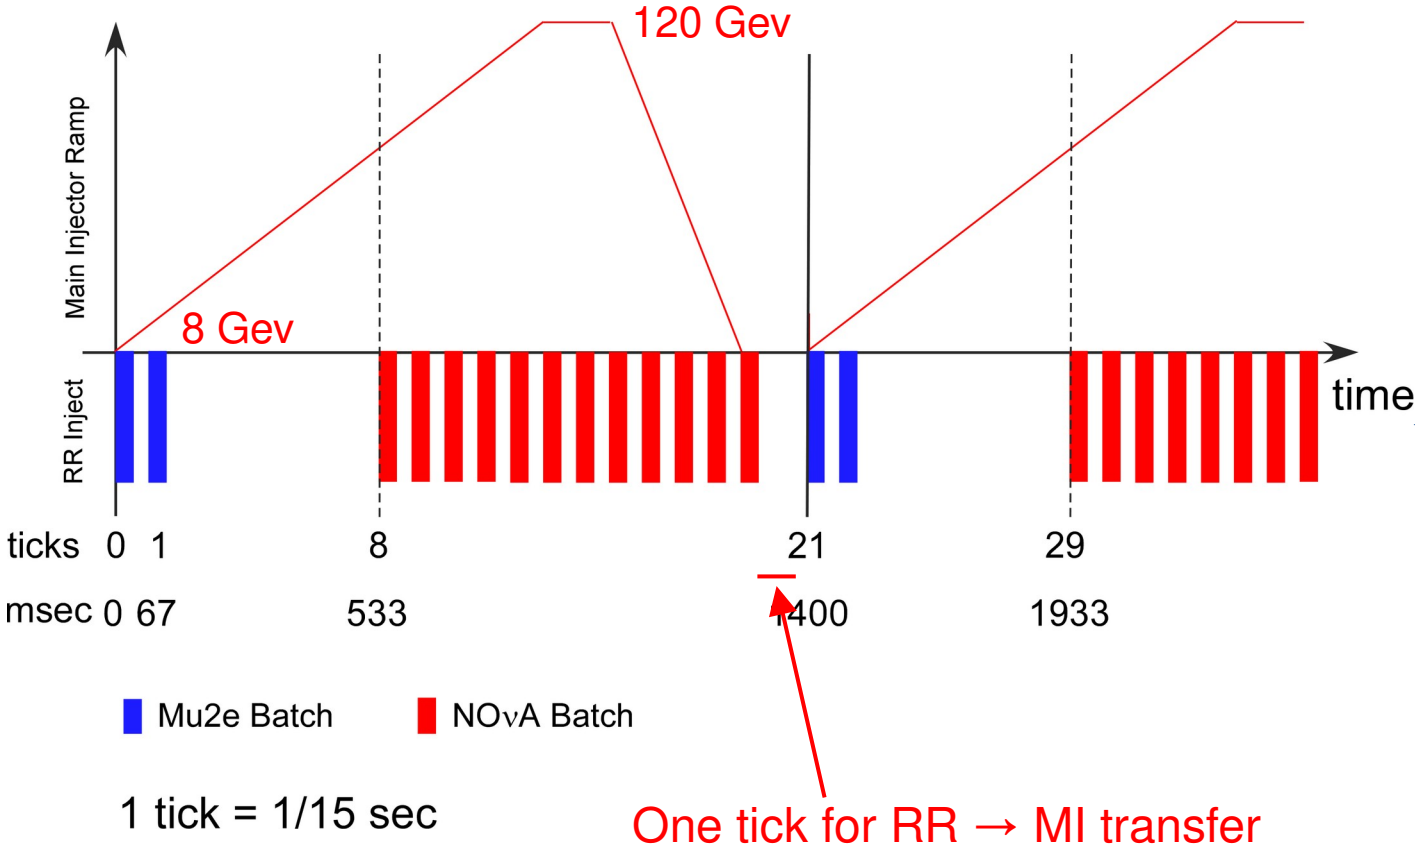


1 tick = 1/15 sec

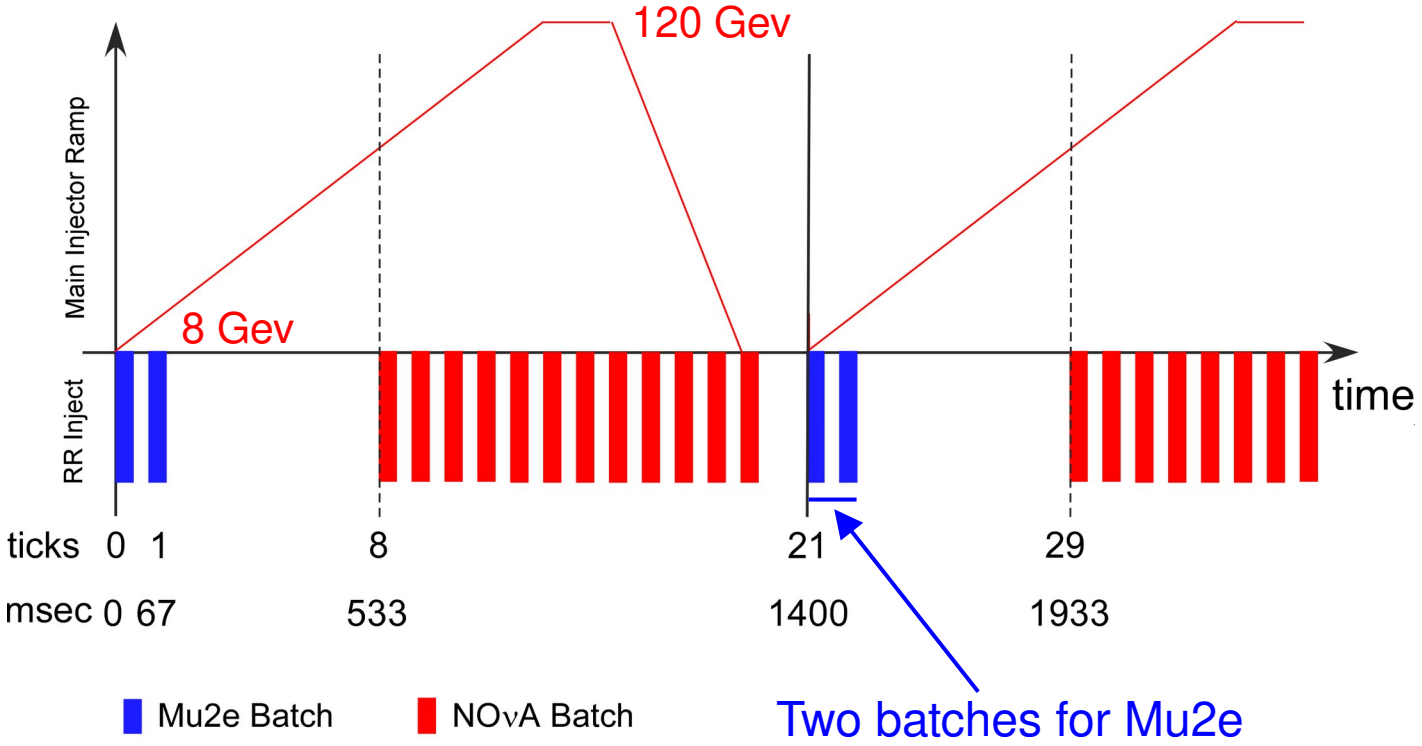
All our machine timelines are built around moving 12 successive Booster batches to the MI – how does this impact muons?



All our machine timelines are built around moving 12 successive Booster batches to the MI – how does this impact muons?

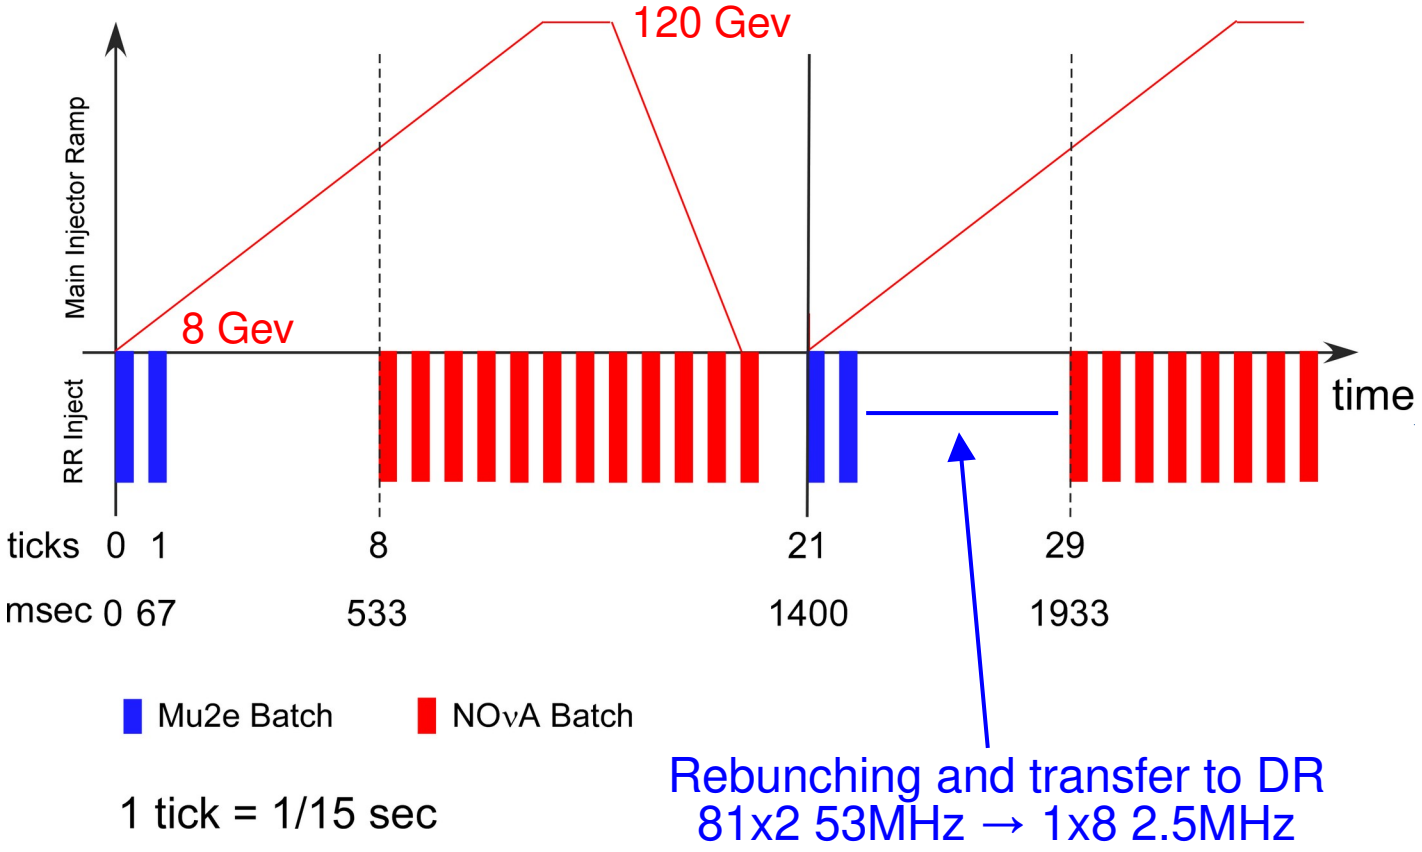


All our machine timelines are built around moving 12 successive Booster batches to the MI – how does this impact muons?

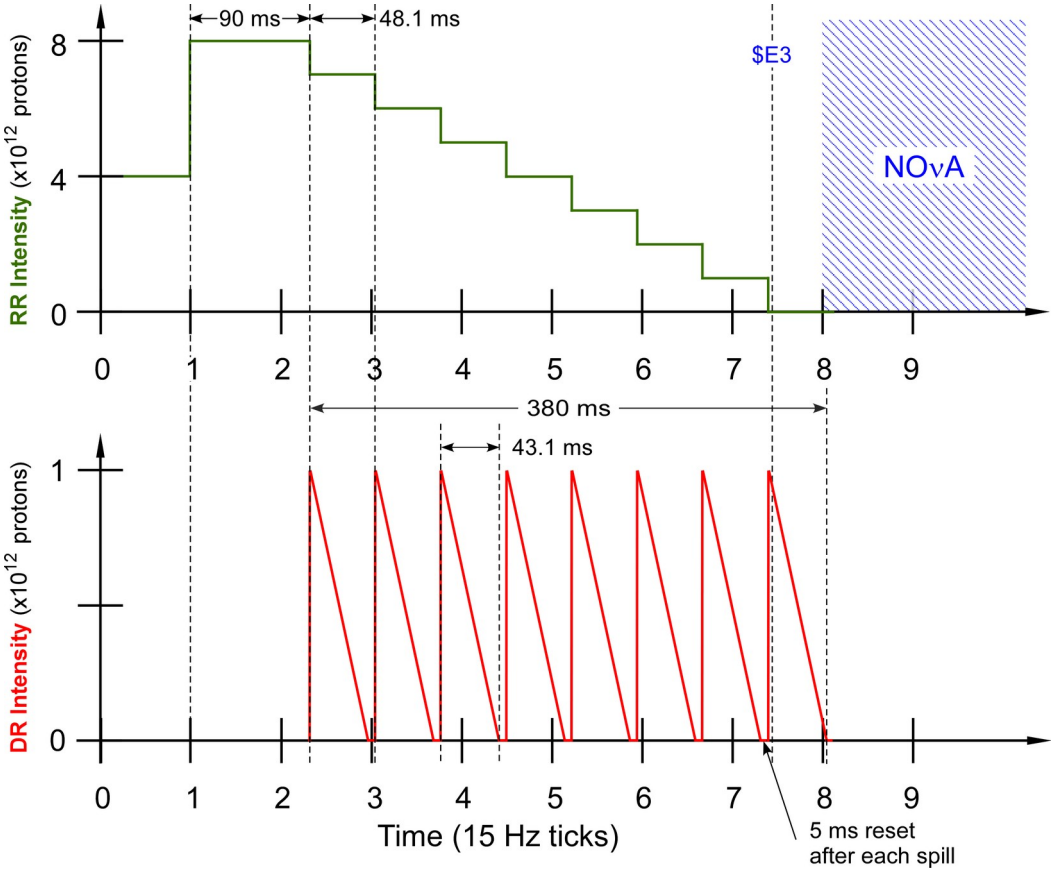


1 tick = 1/15 sec

All our machine timelines are built around moving 12 successive Booster batches to the MI – how does this impact muons?



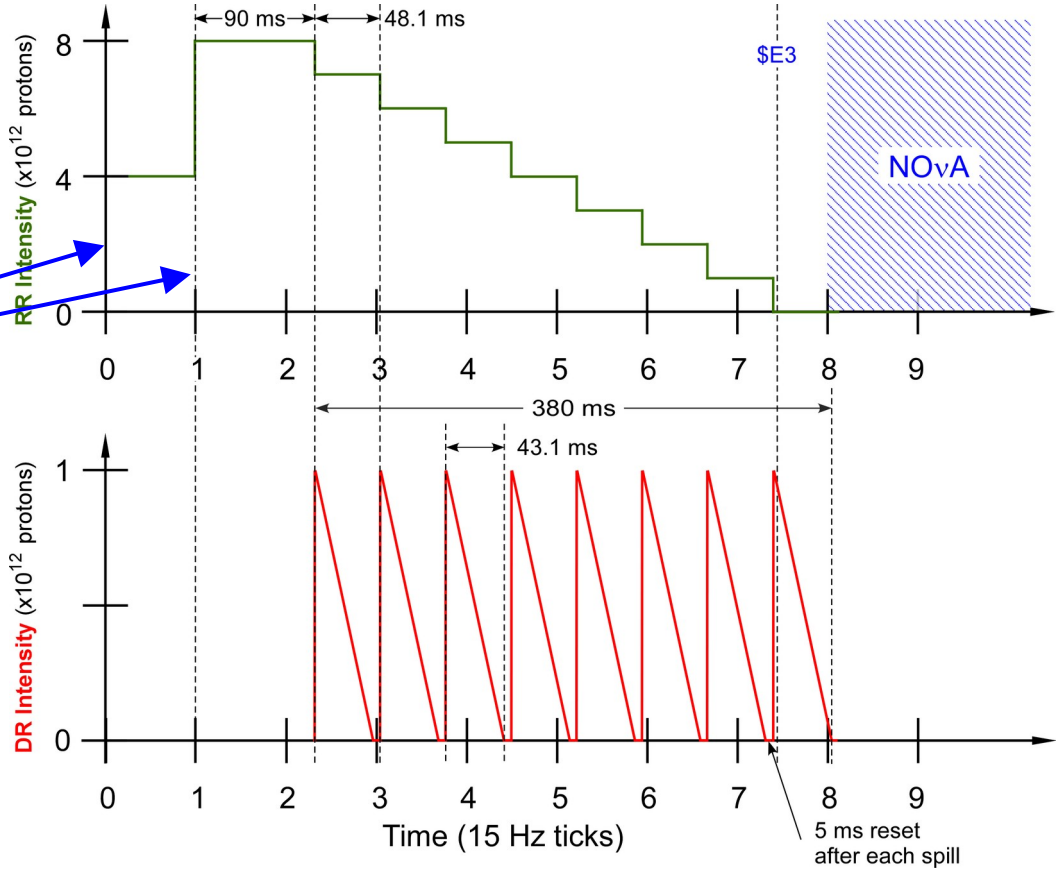
Beam to Mu2e is resonantly extracted from the DR over 8 ticks



Fermilab

Beam to Mu2e is resonantly extracted from the DR over 8 ticks

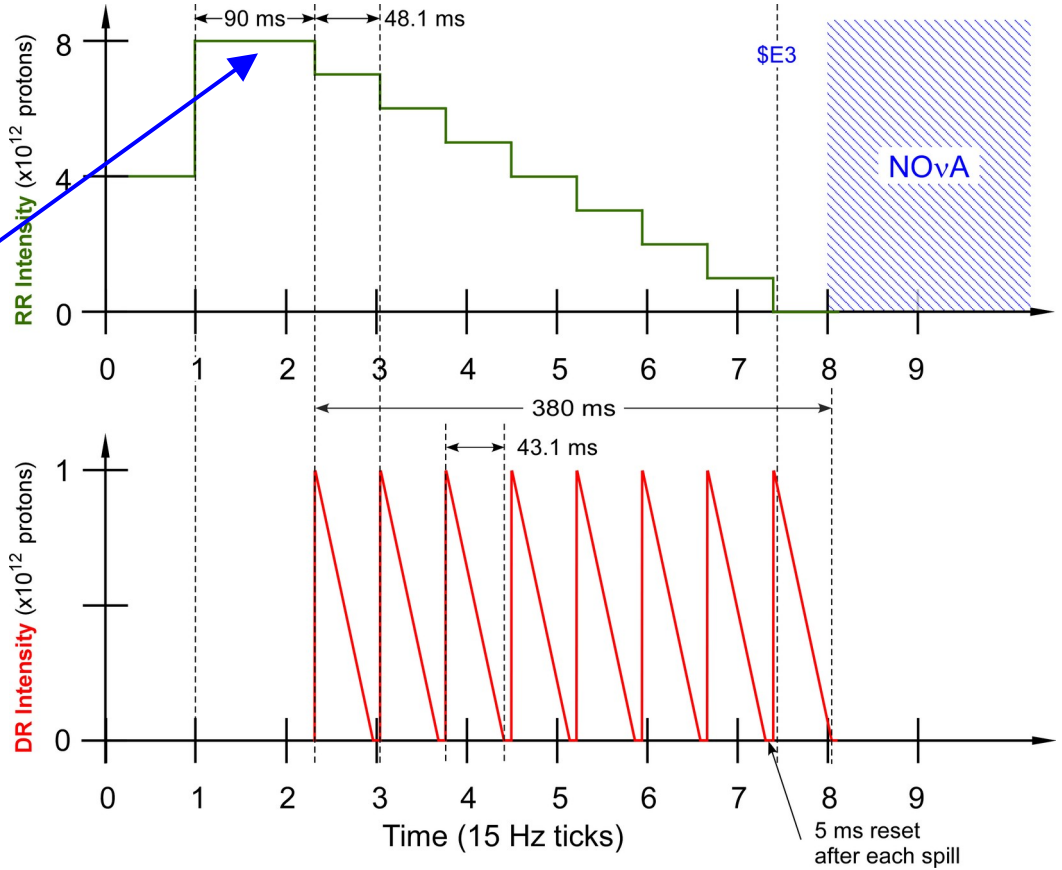
Two batches from Booster



Fermilab

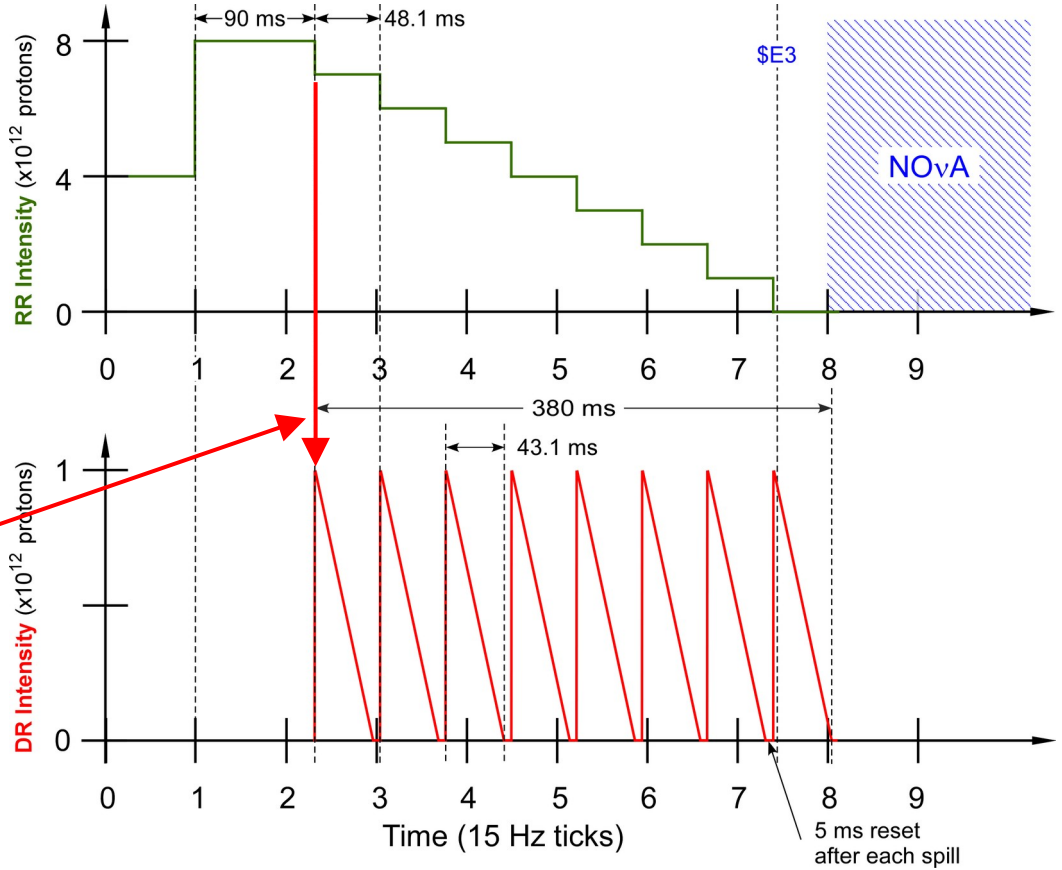
Beam to Mu2e is resonantly extracted from the DR over 8 ticks

Rebatching takes >1 15Hz tick!!!



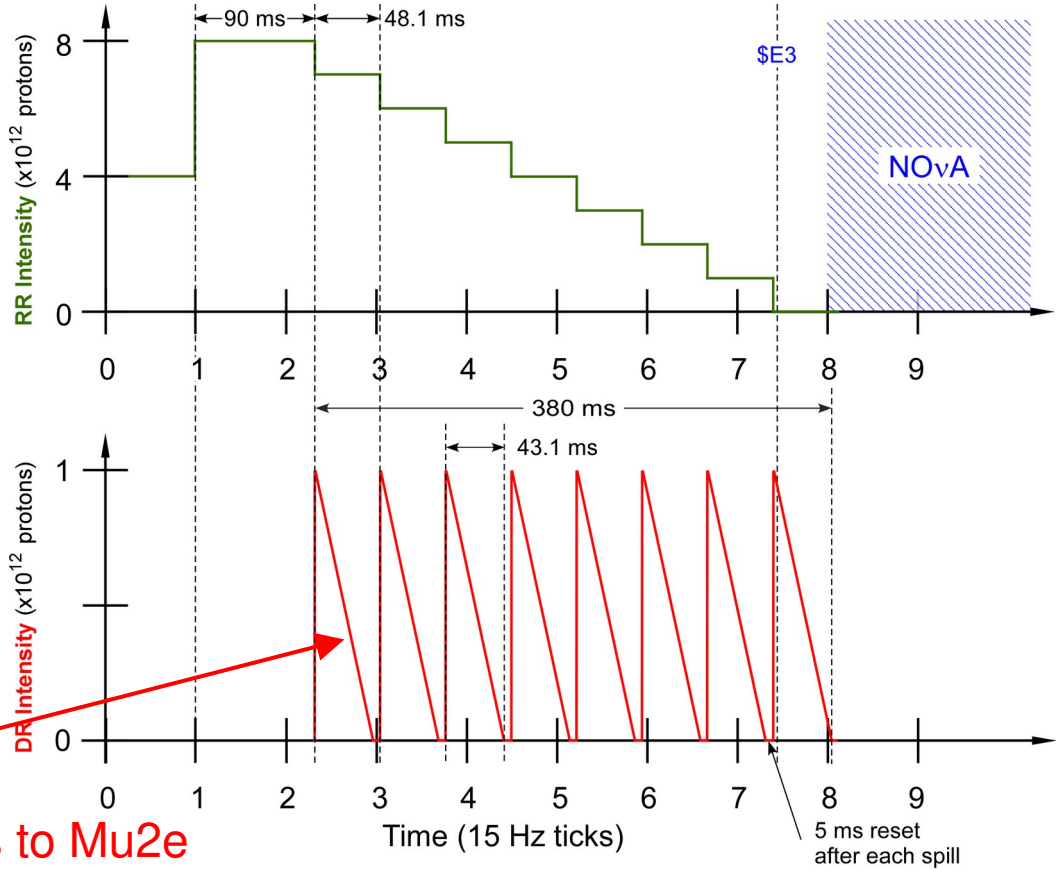
Fermilab

Beam to Mu2e is resonantly extracted from the DR over 8 ticks



Move one of the new batches to DR
2.5MHz → 2.36MHz!

Beam to Mu2e is resonantly extracted from the DR over 8 ticks

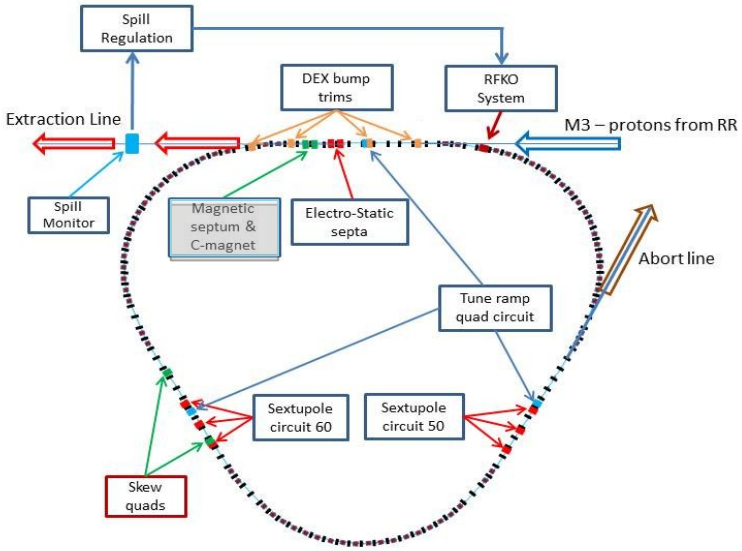


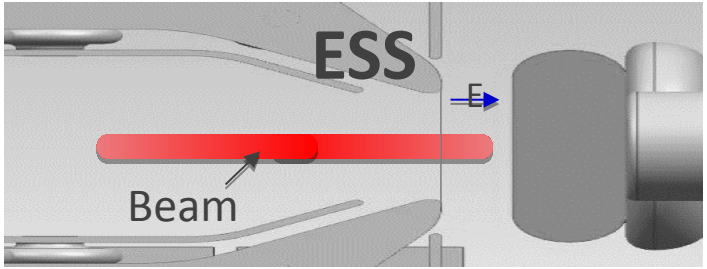
Resonant extraction ~25-30k pulses to Mu2e

Fermilab

Mu2e resonantly extracts from the delivery ring

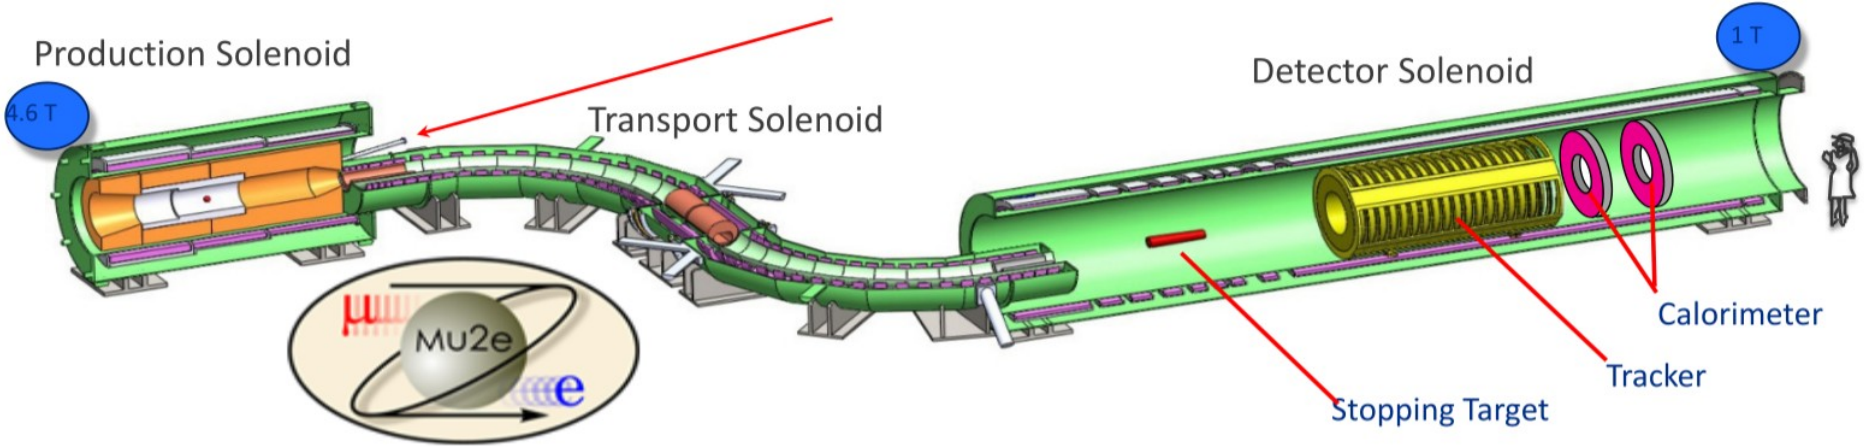
- Quadrupoles intentionally drive a 1/3 integer resonance in the horizontal tune.
- Sextupoles induce a controlled beam instability.
- Septum foils peel off a bunch each turn.
- Dynamic spill regulation control is accomplished by tune corrections and RFKO.
- Full extraction occurs over ~25-30k turns.
- Remaining beam is dumped, and the cycle starts again.



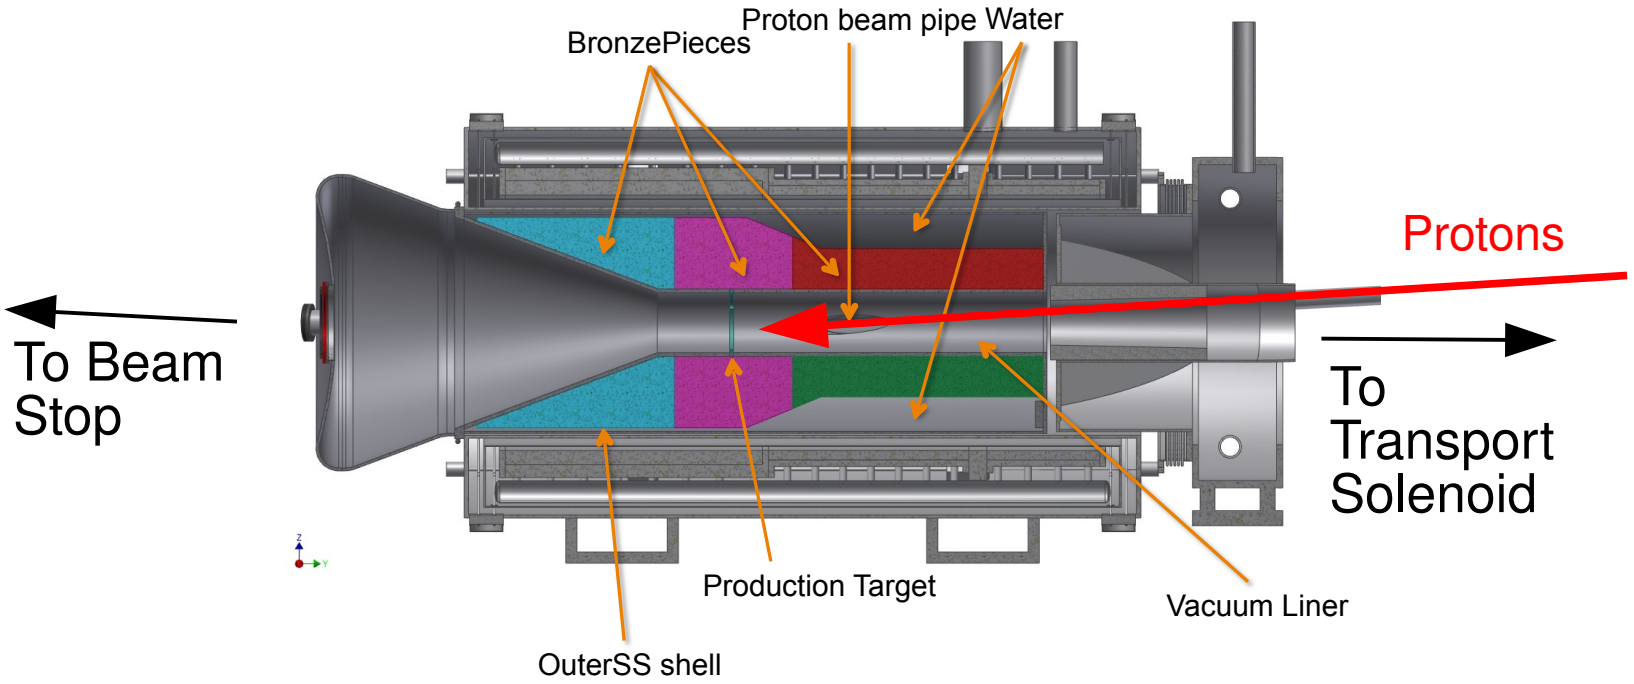


The delivery ring orbital period – 1695ns – drives the interpulse spacing in Mu2e, and is a nearly ideal match to the muonic aluminum lifetime of 864ns.

Twenty slides ago, I showed you this picture

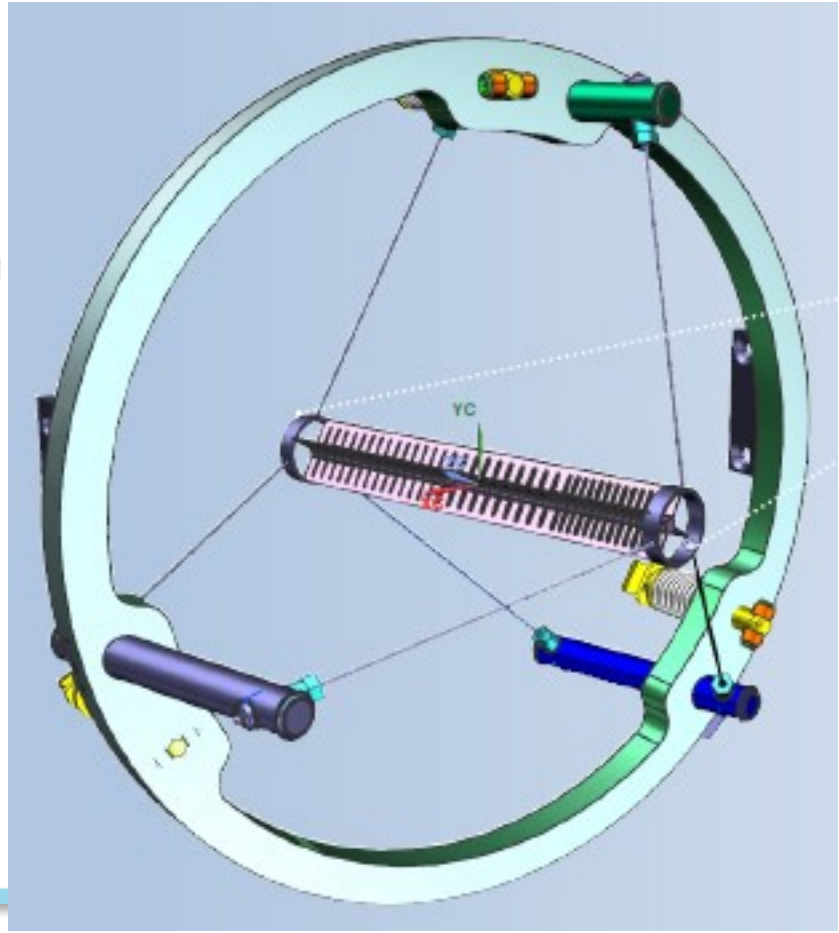


The production target is mounted inside a high field Production Solenoid, and we capture and transport backward muons

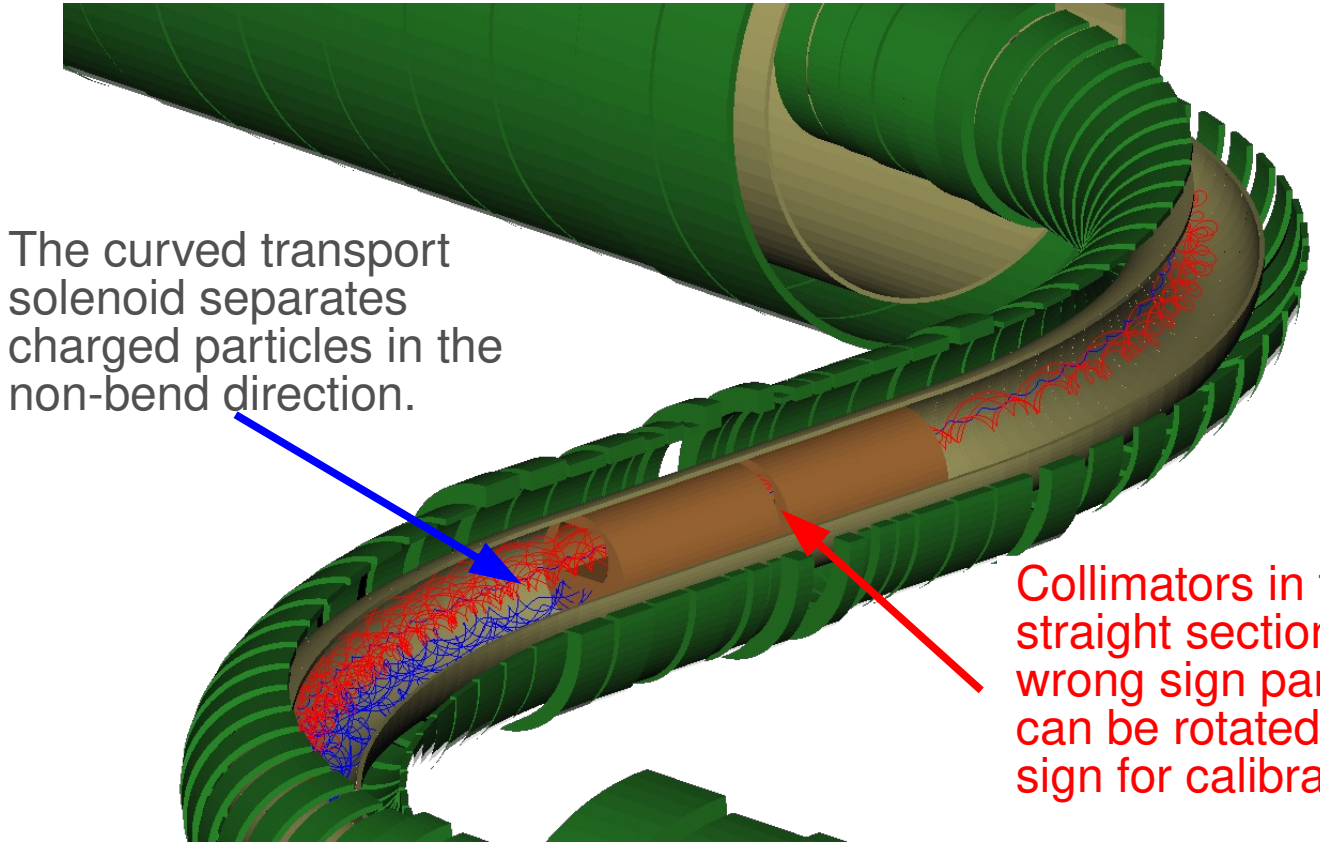


The production target is a radiatively cooled tungsten structure

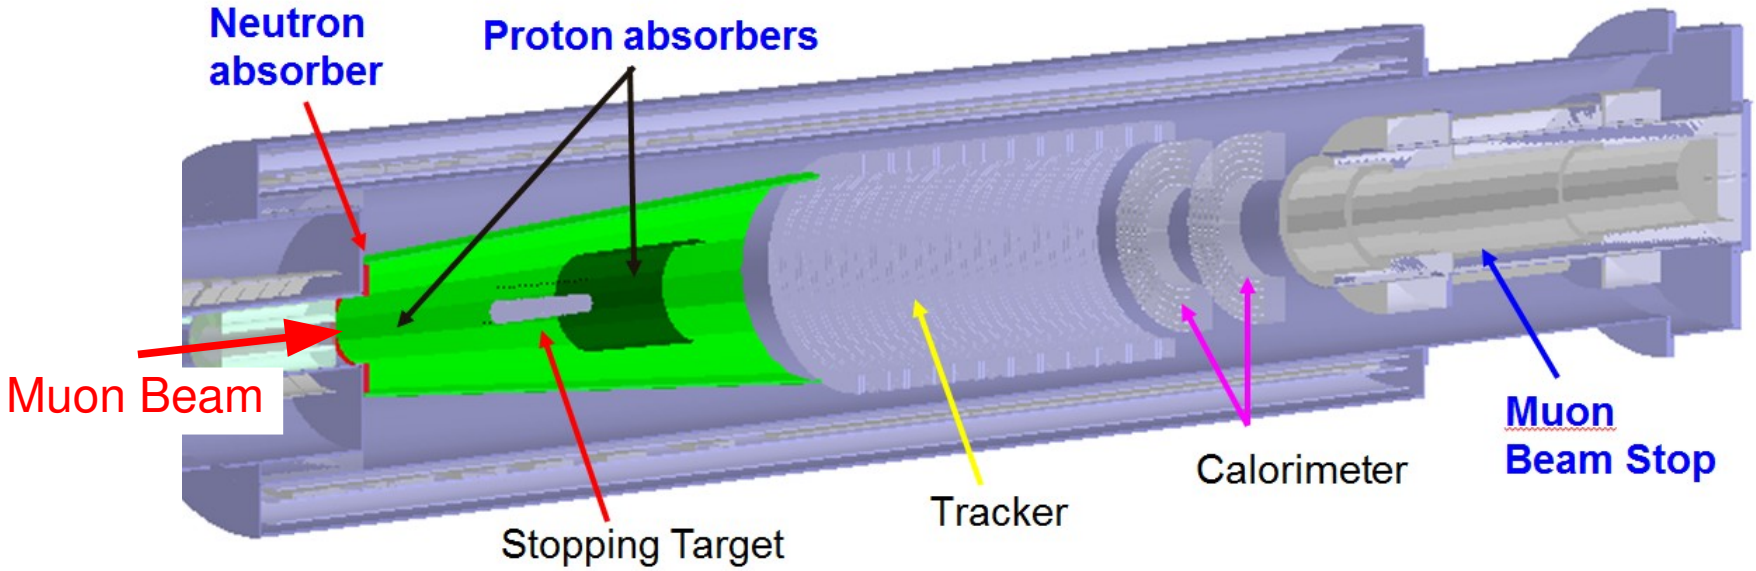
- Bicycle wheel support
- LaO_2-doped Tungsten, core is EDMed from single rod
- Longitudinally segmented cylinder (stress management):
  - 3.15 mm radius, 160+60 mm length
- Longitudinal fins (structure and thermal management)
- 1mm tungsten spokes
- ~ 700 W power absorption
- ~ 1500 K temperature



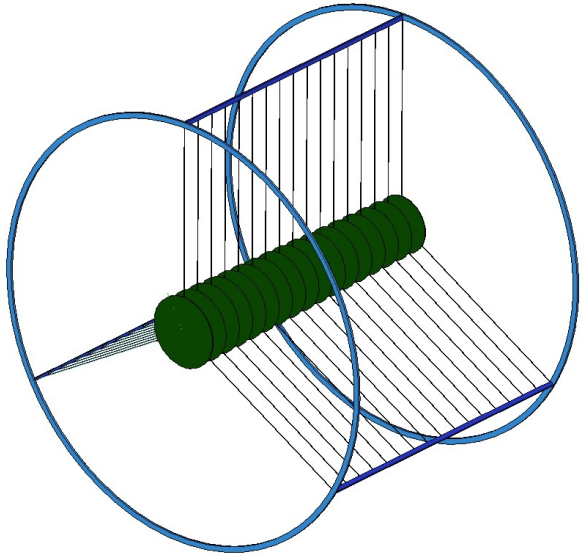
The Transport Solenoid sign-selects with a collimator

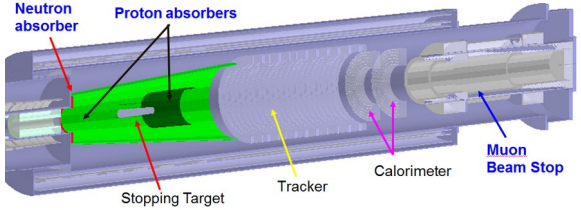


The Detector Solenoid is the heart of the experiment



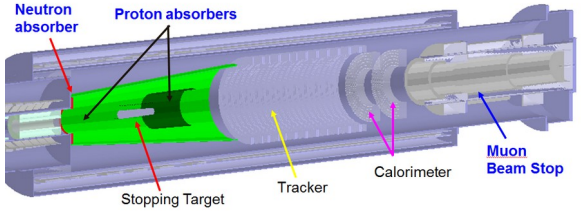
The Detector Solenoid is the heart of the experiment

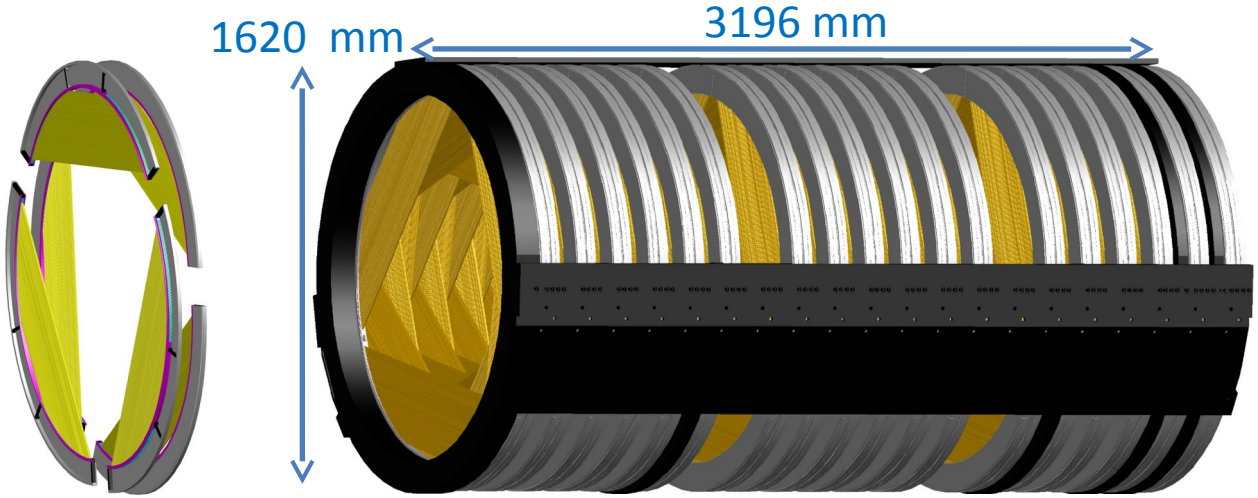




The stopping target is 17 Al foils to intercept and stop the secondary beam

The Detector Solenoid is the heart of the experiment

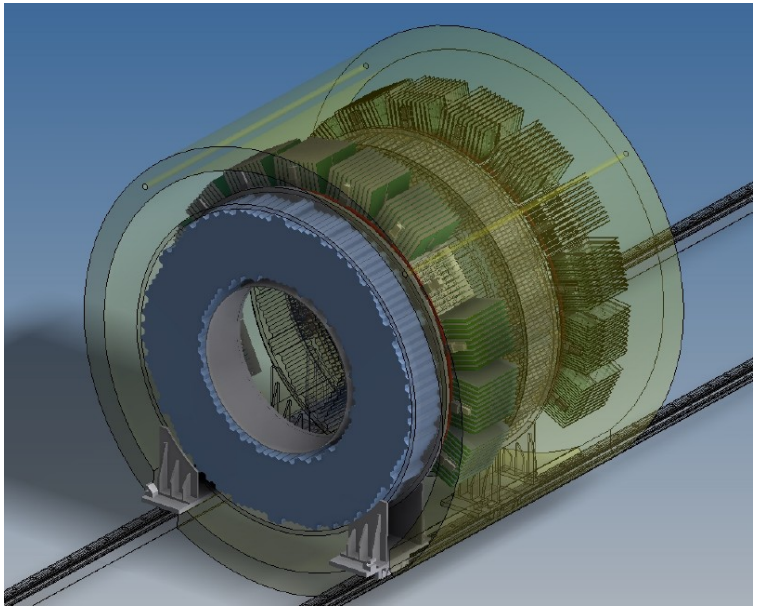


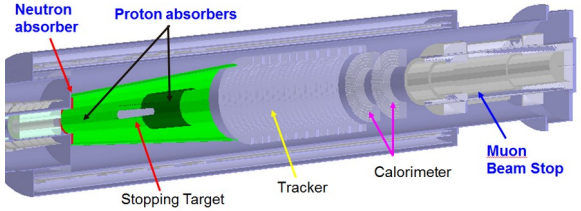


The electron tracker is a low mass straw tube design with 18 stations of tubes transverse to the secondary beam, with 21,000 straws in total.

It provides precision momentum measurement.

The Detector Solenoid is the heart of the experiment



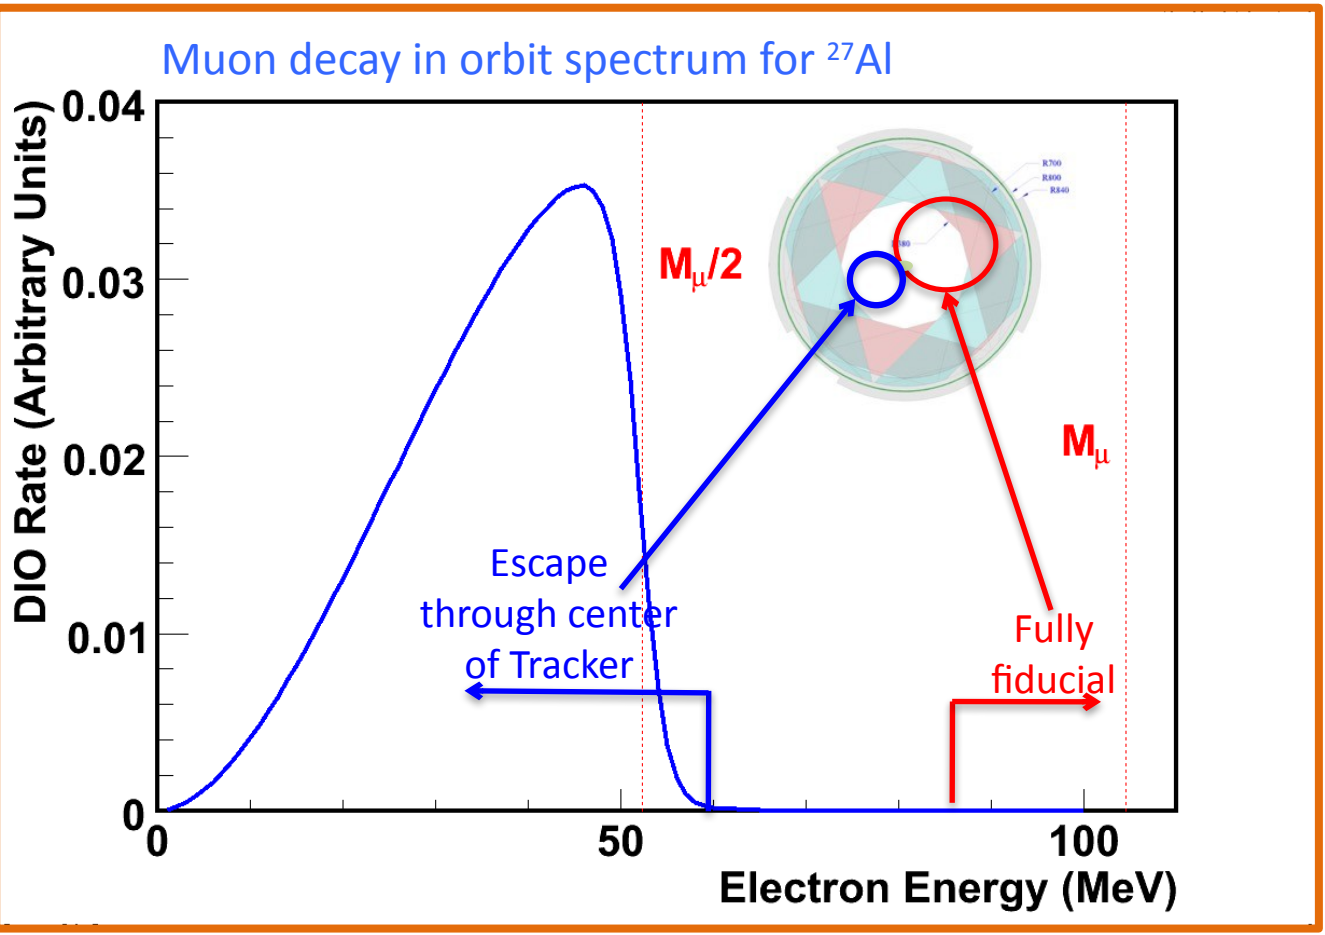


The calorimeter is a two layer, annular, undoped CsI crystal calorimeter.

It provides precision timing and particle ID

Detectors are uninstrumented along the axis of the solenoid

The vast majority of remnant beam, brehmstrahlung, and muon decay products escape down this central hole and are captured in a muon beam stop designed to prevent “back splash”



Mu2e running will be split by the LBNF shutdown

Construction should complete in 2025, with commissioning and Run 1 physics data in 2026-2027.

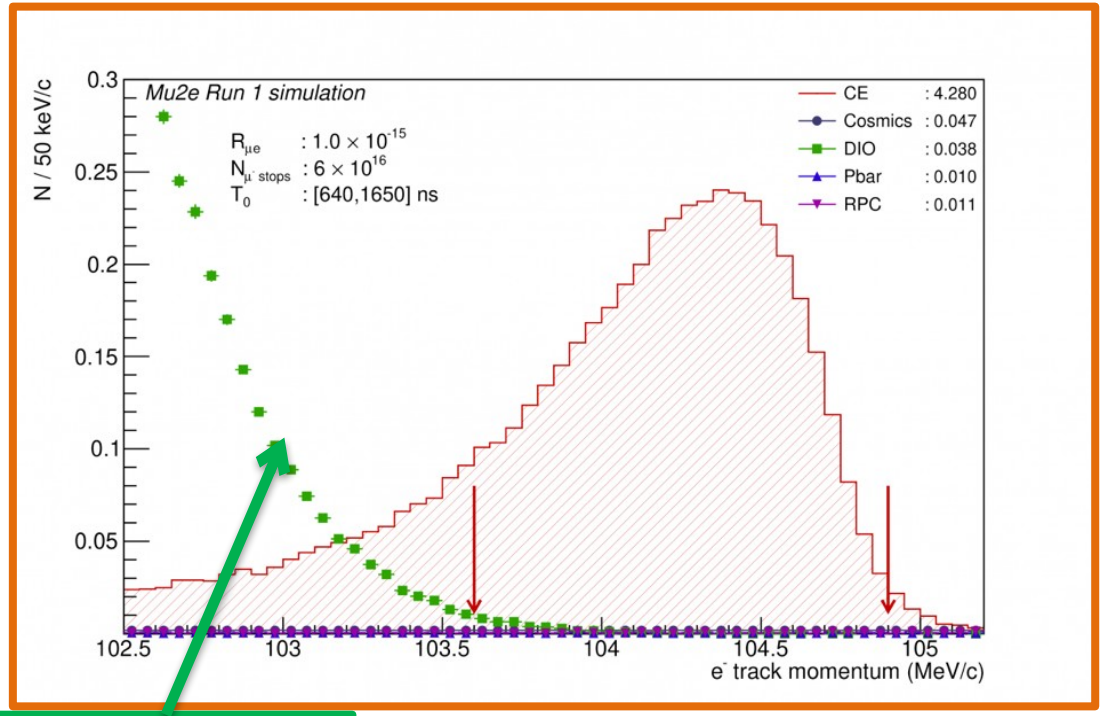
Recently completed a sensitivity estimate for Run 1:

- 5σ discovery R = 1.1 x 10^{-15}
- 90% CL R < 5.9 x 10^{-16}
- 1000x better than SINDRUM-II
- Paper to be submitted to Universe

Run 2 will commence in 2029 with a goal to improve the measurement to 10000x better than SINDRUM-II.

For the full dataset, our expected sensitivity

- 90% CL R < few x 10^{-17}



Fermilab

To summarize…

- Fundamental muon physics today is focused on CLFV searches
  - $\mu \rightarrow e\,\gamma$
  - $\mu \rightarrow eee$
  - $\mu^- N \rightarrow e^- N$
- Mu2e and COMET are friendly competition in the conversion search with much shared DNA
  - Both aim for a 10,000x improvement over SINDRUM-II
- We're either going to discover new physics in the next few years, or we'll provide a nearly unprecedented improvement in sensitivity, either of which beg for a next generation experiment
  - Although I couldn't talk about them today, there are ideas to gain an additional 2-3 orders of magnitude with future searches in these and other channels

Thanks for your interest and attention!
