Physics Motivation of sub-GeV Dark Sector Search at DUNE

- Exclusion plot of WIMP direct searches shows an inaccessible region in terms of mass below sub-GeV region.
- Experimentally, this limit originated from detection threshold limit of DM-nucleon scattering in LXe detectors.
- Theoretically, the WIMP scenario imposes a limit of around 2 GeV by resulting in an absurd relic abundance of dark matter when the mass of dark matter goes below 2 GeV.

Light Dark Matter Scenario

- How do we go beyond the WIMP paradigm?
 - Introduce a new U(1) gauge symmetry and corresponding gauge boson called 'dark photon'.
 - We call the new interaction between Standard Model (SM) photon and dark photon as 'portal interaction'.
 - We can detect this DM by observing <u>recoiled particles in ND by invisible</u>

Simulation Work-flow

_ _ _ _ _

	Signal	Background
Event Generation	p-C interaction (GEANT4/DMG4/PETTITE/…) → Dark matter flux @ ND	p-C interaction (G4LBNE simulation) → DUNE neutrino flux @ ND
	GENIE-MC w/ DM module Simulate DM-LAr interaction → Recoiled electrons	GENIE-MC Simulate v-LAr interaction → Recoiled electrons, mis-ID possibilities
Detector Study	Detector response edep-sim	
	Reconstruction – ND software	
	Sensitivity estimation taking into account experiment details

Future Plan

- 1) Detailed target and dump simulation (with magnetic horn implementation)
- 2) GENIE-MC with ND geometry
- 3) Revisit signal study with PETITE
- 4) <u>Reconstruction study using ND software</u>
- 5) Limit (or sensitivity) calculation
