Applied Antineutrino and Dark Matter Science - Underground Facility Needs

Adam Bernstein
Rare neutral particle detection connects Nuclear Security to Neutrino and Dark Matter Physics

Fissile Material Search and Monitoring are top priorities for global nuclear security

Reactor antineutrino monitoring via inverse beta detectors

Reactor monitoring via coherent scatter; improved fissile material monitoring

1-10 MeV antineutrinos

1 keV to 10 MeV Neutrons and Gamma-rays

Neutrino oscillations and sterile neutrinos

Dark Matter signatures: Axions and WIMPS

Dark Matter and Neutrino Physics are top priorities in 21st century physics

Nuclear Security and Nuclear Science both require improved keV to MeV-scale neutral particle rare event detectors
Nuclear Security applications that require deep underground facilities

The **WATCHMAN (Water Cherenkov Antineutrino Monitoring)** project is now in its first phase in the United States.

- **Goal:** demonstrate sensitivity to reactor antineutrinos using a gadolinium-doped water detector at 0.1-1 kilometer standoff from a 10-150 MWt US research reactor, or several kilometers from a 3000 MWt scale US commercial power reactor.

- **Current work in the US:** to identify site, measure backgrounds, and develop a design envelope for the detector.
Perry Reactor Nuclear Generating Station to IMB cavern in the Fairport Salt Mine (Ohio)

1. Existing 20 m cubic cavern – other excavations possible
2. 1570 m.w.e.
3. 13 km standoff
4. 3875 MWth

1. The only mine in the United States within 20 km of a reactor
2. Ideal for this demonstration - ~10-fold cost-savings compared to new excavation at shallow depth
3. Would be the only US detector sensitive to supernova antineutrinos
4. Upgraded detector physics potential for geo-antineutrinos and mass hierarchy being investigated.

A preliminary look at the antineutrino spectrum - 1 year of operation, errors not yet incorporated

Plot courtesy Steve Dye, Hawaii Pacific Univ.
WATCHMAN possible non-US deep site: the Cleveland Potash mine in Boulby, England

- 2800 mwe depth
- 20-25 km standoff
- Hartlepool reactor thermal power = 1570 MWth (2 cores)
- Some sensitivity to oscillations with LS or WBLS upgrade

A: unoscillated and distorted spectrum showing effects due to "theta12" oscillations (overall suppression) and theta13 (small wiggles). Resolution is 3%/sqrt(E). Distance is 25 km.
B: Ratio showing low energy suppression due to theta12. Error bars assume 20 kton-yr exposure at Boulby. The theta12 sensitivity comes from the low energy shape.
C: With pure water, this is still there but much less apparent due to 20%/sqrt(E) resolution and Cherenkov threshold.
Nuclear Forensics and HEP Facility requirements overlap

**Science goals**
- Measurement of intrinsic backgrounds in materials is essential to current and future rare event detection experiments
- Depths similar to those at which experiments are deployed – ~500-5000 mwe

**Common Facility needs**
- Depth - to suppress backgrounds from muons/muogenic neutrons
- Well-characterized ambient backgrounds
- Background-suppressed HPGe detectors
- Alpha/beta spectroscopy
- Sample preparation and wet chemistry
- Muon veto and gamma/neutron shielding

**Nonproliferation goals**
- Characterizing trace fissile content of various materials for a range of nonproliferation goals
- Many nonproliferation needs are met by **relatively shallow depth** underground facilities
- The most pressing issue is **expertise**: nonproliferation sponsors maybe willing to fund underground facilities for this reason

Example: **Assay and Acquisition of Radiopure Materials (AARM)** program at Homestake

Example: **Naval Research Lab facility at Kimballton Mine** – joint with Virginia Institute of Technology
## Summary and conclusions

### Remote Reactor Monitoring Facility need
- A new US nonproliferation initiative requires a 500-5000 mwe site to demonstrate sensitivity to reactor antineutrinos using a large Gd-water-Cherenkov detector
- Paves the way for future very large scale detectors which exclude the existence of small reactors in wide geographical regions
- The 1600 mwe Fairport mine near Cleveland Ohio and the 2800 mwe Boulby mine in England are viable deep underground options
- A 1-10 kiloton-scale device will have world-class supernova sensitivity
- Upgrading to LS may enable geo-antineutrino and limited oscillation sensitivity
- Detector R&D well suited for Hyper-K and other large water detectors

### Nuclear Forensics Facility Needs
- Low background detectors in underground are required for several applications
- Much work can be done at relatively shallow depth sites – 50-300 mwe
- Nonproliferation sponsors might be persuaded to support operation of deeper sites in order to maintain US expertise in rare event detection
- AARM collaboration in the US and the CELLAR consortium in Europe are examples of cooperation among disciplines and sites (see Cushman talk)
