![](_page_8_Figure_1.jpeg)

![](_page_9_Picture_0.jpeg)

## The Motivation

![](_page_9_Picture_2.jpeg)

Alexander Radovic

![](_page_10_Picture_0.jpeg)

# Why Study Neutrinos?

Neutrino oscillations raises as many questions as it answers:

- Why is lepton sector mixing much larger than quark sector mixing?
- What is the hierarchy of neutrino masses and how does this effect searches for a majorana neutrino?
- Is there CP violation in the lepton sector? Could it be large enough to explain observed matter antimatter asymmetry of our universe?

![](_page_10_Picture_6.jpeg)

![](_page_10_Picture_7.jpeg)

![](_page_11_Picture_0.jpeg)

Measuring neutrino oscillations is all about measuring how neutrinos change between different lepton flavor states as a function of distance traveled and neutrino energy.  $1.27\Delta m_{atm}^2 L$ 

$$P(\nu_{\mu} \rightarrow \nu_{\mu}) \approx 1 - \frac{\sin^2(2\theta_{23})}{\sin^2}$$

![](_page_11_Figure_4.jpeg)

![](_page_11_Picture_5.jpeg)

![](_page_12_Picture_0.jpeg)

- That means that any oscillation analysis can benefit from precise identification of the interaction in two ways:
  - Estimating the lepton flavor of the incoming neutrino.
  - Correctly identifying the type of neutrino interaction, to better estimate the neutrino energy, aka is it a quasi elastic event or a resonance event?

![](_page_12_Figure_5.jpeg)

![](_page_12_Picture_6.jpeg)

![](_page_13_Picture_0.jpeg)

- Furthermore we as we want to accurately estimate the neutrino energy we need precise & robust reconstruction:
  - Identifying reconstructed objects in the event.
  - R-CNNs to isolate activity related to the interaction of interest.
  - Ultimately semantic segmentation to combine local and global information smoothly for hit-by-hit identification.

![](_page_13_Picture_6.jpeg)

![](_page_13_Figure_7.jpeg)

![](_page_13_Picture_8.jpeg)

![](_page_14_Picture_0.jpeg)

- Our detectors are also often the perfect domain:
  - Large ~uniform volumes where spatially invariant response is a benefit.
  - Usually only one or two detector systems.

![](_page_14_Figure_5.jpeg)

![](_page_14_Picture_6.jpeg)

![](_page_15_Picture_0.jpeg)

- Our detectors are also often the perfect domain:
  - Large ~uniform volumes where spatially invariant response is a benefit.
  - Usually only one or two detector systems.

![](_page_15_Figure_5.jpeg)

![](_page_16_Picture_0.jpeg)

### NOvA

![](_page_16_Picture_2.jpeg)

Alexander Radovic

# X NOvA Event Topologies

![](_page_17_Figure_1.jpeg)

1 radiation length = 38cm (6 cell depths, 10 cell widths)

![](_page_18_Picture_0.jpeg)

## Our Input

Our input "image", is a pair of maps of the hits in a tight space/time window. One for the X view and another for the Y view. Each "pixel" is the calibrated energy response in that cell. All "images" have the same dimensions- 100 planes by 80 cells.

![](_page_18_Figure_3.jpeg)

![](_page_18_Picture_4.jpeg)

# The Training Sample

![](_page_19_Figure_1.jpeg)

4.7 million, minimally preselected simulated events, pushed into LeveIDB databases: 80% for training and 20% for testing. Rescale calibrated energy depositions to go from 0 to 255 and truncate to chars for dramatically reduced file size at no loss of information Fine tuned with 5 million

cosmic data events taken from an out of beam time minimal bias trigger.

## Our Architecture

Based on the first googlenet. Largest innovation is splitting each view into a separate sequence of layers and concatenating the outputs near the end of the network. Named "Convolutional Visual Network", or **CVN**.

The architecture attempts to categorize events as {v<sub>µ</sub>, v<sub>e</sub>, v<sub>τ</sub> } × {QE,RES,DIS}, NC, or Cosmogenic.

Utilizes a "softmax" output.

Built in the excellent CAFFE framework: <u>http://caffe.berkeleyvision.org/</u>

![](_page_20_Figure_6.jpeg)

## Conclusions

- The first high energy particle physics measurement to use a convolutional neural network learning was a neutrino oscillation measurement from the NOvA experiment!
- Just the tip of the iceberg at NOvA! Huge amounts of room to optimize our classification network, and to explore other applications of convolutional neural networks.
- Almost every neutrino experiment seems to be investigating the use of CNNs in their analysis and reconstruction of neutrino interactions, set to be particularly vital for liquid argon detectors which are a core part of the planned DUNE LBL oscillation experiment.

![](_page_40_Picture_4.jpeg)

NOvA Status and Future

### v<sub>e</sub> candidates, when & where?

![](_page_59_Figure_1.jpeg)

![](_page_60_Figure_0.jpeg)

## Simulation

- Highly detailed end-to-end simulation chains:
- Beam hadron production, propagatio, neutrino flux: FLUKA/FLUGG
- Cosmic ray flux: CRY
- Neutrino Interactions and FSI modeling: GENIE
- Detector Simulation: GEANT4
- Readout electronics and DAQ: Custom simulation routines

![](_page_60_Figure_8.jpeg)

![](_page_60_Picture_9.jpeg)

![](_page_61_Picture_0.jpeg)

## Reconstruction

#### Three key pieces:

- Vertexing: use lines of energy deposition formed with hough transforms to find intersections
- Clustering: find clusters in angular space around the vertex and merge views via topology and prong dE/dx
- Tracking: Trace particle trajectories using a kalman filter, example below

![](_page_61_Figure_6.jpeg)

![](_page_61_Figure_7.jpeg)

![](_page_61_Picture_8.jpeg)
